Newton's Method for Solving a Nonlinear Equation

Scenario: Have an equation $y(x) = 0$, but it is too messy to solve directly. You do have an initial guess at the correct value of x . It is close, but wrong. For example, solve:

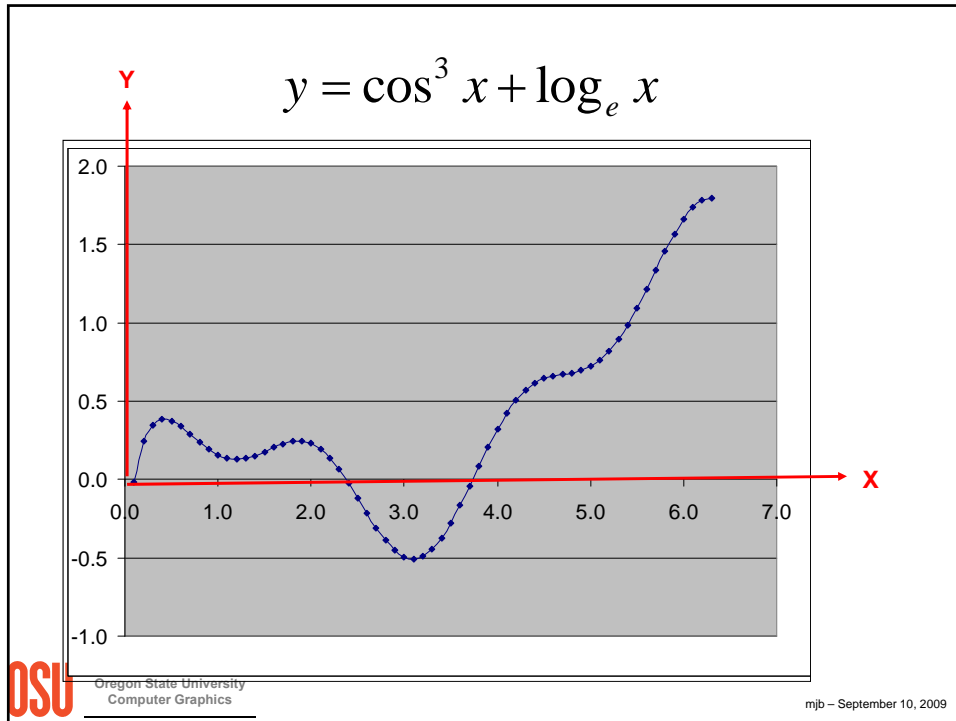

$$y(x) = \cos^3 x + \log_e x = 0$$

Starting with $x=6$

Newton's Method for Solving a Nonlinear Equation

You can take the x you have and plug it into the equation to produce y_{have} . Now what?

From calculus, we know that:

$$\frac{dy}{dx} \approx \frac{\Delta y}{\Delta x} \quad \text{or} \quad \Delta y = \frac{dy}{dx} \Delta x$$

The required Δy is:

$$\Delta y = y_{want} - y_{have} = 0. - y_{have}$$

So that: $\frac{dy}{dx} \Delta x = y_{want} - y_{have} = 0. - y_{have}$

Or: $\Delta x = \frac{-y_{have}}{\frac{dy}{dx}}$

We will use that to find the next value of x to try, and then repeat the process:

$$x_{have} = x_{have} + \Delta x$$

$$y_{have} = y(x_{have})$$

Watching Newton's Method Work

$$y = \cos^3 x + \log_e x = 0$$

$$\frac{dy}{dx} = -3 * \sin x * \cos^2 x + \frac{1}{x}$$
