Simple Keyframe Animation

Approaches to Animation

1. Motion Capture (“MoCap”)
2. Using the laws of physics (we’ll use this in the spring-based motion)
3. Using functional (target-driven) animation (we’ll use this in collision avoidance)
4. Using keyframing

Keyframing

Keyframing involves creating certain key positions for the objects in the scene, and then the program later interpolating the animation frames in between the key frames.

In hand-drawn animation, the key frames are developed by the senior animators, and the in-between frames are developed by the junior animators.

In our case, you are going to be the senior animator, and the computer will do the in-betweening.

But, first we need to look into the mathematics of smooth curves . . .

Bézier Curves: the Derivation

One parametric line:

\[ P_t = (1-t)P_0 + tP_1 \]

Two parametric lines:

\[ P_{t1} = (1-t)P_0 + tP_1 \]
\[ P_{t2} = (1-t)P_2 + tP_3 \]

Two parametric lines, blended:

\[ P_{t3} = (1-t)P_0 + tP_1 \]
\[ P_{t4} = (1-t)P_2 + tP_3 \]

Note: we are not actually going to use Bézier curves for the animation, but they are a good place to start to understand how smooth curves work.
Bézier Curves: the Derivation

Three parametric lines, blended:

\[ P_i = t_i P_0 + (1 - t_i) P_1 \]
\[ P_i = t_i P_0 + (1 - t_i) P_2 \]
\[ P_i = t_i P_0 + (1 - t_i) P_3 \]

\[ P_{11} = (1 - t) P_0 + t P_1 \]
\[ P_{11} = (1 - t) P_0 + t P_2 \]
\[ P_{11} = (1 - t) P_0 + t P_3 \]

\[ P_{11} = (1 - t) P_0 + t P_1 \]
\[ P_{11} = (1 - t) P_0 + t P_2 \]
\[ P_{11} = (1 - t) P_0 + t P_3 \]

So How Do Smooth Curves Work in Computer Graphics?

A Small Amount of Input Change Results in a Large Amount of Output Change

The General Form of Cubic Curves

\[ P(t) = (1-t)^3 P_0 + 3(1-t)^2 t P_1 + 3(1-t) t^2 P_2 + t^3 P_3 \]

Another Approach: Coons (also called Hermite) Cubic Curves

Another approach to specifying the 4 pieces of information would be to give a start point, an end point, a start parametric slope, and an end parametric slope.

\[ \dot{P}_0 = \frac{dP}{dt} \]
\[ \ddot{P}_1 = \frac{dP}{dt} \]

Rearranging gives A, B, C, and D for the Bézier curve:

\[ A = P_0 \]
\[ B = -3P_0 + 3P_1 \]
\[ C = 3P_0 - 6P_1 + 3P_2 \]
\[ D = -P_0 + 3P_1 - 3P_2 + P_3 \]
Now, Let's Apply this to the Y Translation of a Keyframe Animation

To make this simple to use, our goal is to just specify the keyframe values, not the slopes. We will let the computer compute the slopes for us, which will then result in being able to compute the in-between frames.

Many Professional Animation Packages Make You Sculpt the Slopes (but we won't . . .)

Blender:

Getting the Two End Slopes

To get the slope at a keyframe point, draw a line between one keyframe back from that one and one keyframe ahead.

Do This Same Thing for the X, Y, and Z Translations and the X, Y, and Z Rotations

Instead of Key Frames, I Like Specifying Key Times Better

And, so, I created a C++ class to do it all for you

```cpp
class Keytimes:
    void AddTimeValue(float time, float value);
    float GetFirstTime();
    float GetLastTime();
    int GetNumKeytimes();
    float GetValue(float time);
    void PrintTimeValues();
```
Instead of Key Frames, I Like Specifying Key Times Better

```c
Keytimes Xpos;
int main( int argc, char *argv[] )
{
    Xpos.AddTimeValue( 0.0, 0.000 );
    Xpos.AddTimeValue( 2.0, 0.333 );
    Xpos.AddTimeValue( 1.0, 3.142 );
    Xpos.AddTimeValue( 0.5, 2.718 );
    fprintf( stderr, "%d time-value pairs:
", Xpos.GetNumKeytimes() );
    Xpos.PrintTimeValues();
    fprintf( stderr, "Time runs from %8.3f to %8.3f
", Xpos.GetFirstTime(), Xpos.GetLastTime() );
    for( float t = 0.; t <= 2.01; t += 0.1 )
    {
        float v = Xpos.GetValue( t );
        fprintf( stderr, "%8.3f	%8.3f
", t, v );
    }
}
```

Instead of Key Frames, I Like Specifying Key Times Better

```c
Keytimes Xpos, Ypos, Zpos;
Keytimes ThetaX, ThetaY, ThetaZ;

if( AnimationIsOn )
{
    // # msec into the cycle (0 - MSEC-1):
    int msec = glutGet( GLUT_ELAPSED_TIME ) % MSEC;
    // turn that into a time in seconds:
    float nowTime = (float)msec / 1000.;
    glPushMatrix( );
    glTranslatef( Xpos.GetValue( nowTime ), Ypos.GetValue( nowTime ), Zpos.GetValue( nowTime ) );
    glRotatef( ThetaX.GetValue( nowTime ), 1., 0., 0. );
    glRotatef( ThetaY.GetValue( nowTime ), 0., 1., 0. );
    glRotatef( ThetaZ.GetValue( nowTime ), 0., 0., 1. );
    // draw the object >
    glPopMatrix( );
}
```

Using the System Clock in Display() for Timing

```c
# define MSEC 10000 // i.e., 10 seconds
Keytimes Xpos, Ypos, Zpos,
Keytimes ThetaX, ThetaY, ThetaZ;

if( AnimationIsOn )
{
    // # msec into the cycle (0 - MSEC-1):
    int msec = glutGet( GLUT_ELAPSED_TIME ) % MSEC;
    // turn that into a time in seconds:
    float nowTime = (float)msec / 1000.;
    gPushMatrix();
    gTranslatef( Xpos.GetValue( nowTime ), Ypos.GetValue( nowTime ), Zpos.GetValue( nowTime ) );
    gRotatef( ThetaX.GetValue( nowTime ), 1., 0., 0. );
    gRotatef( ThetaY.GetValue( nowTime ), 0., 1., 0. );
    gRotatef( ThetaZ.GetValue( nowTime ), 0., 0., 1. );
    gPopMatrix();
}
```

A Final Word

If you ever do this “for real”, quaternions are a better way to do the rotations. Quaternions are essentially 4D complex numbers, the details of which are beyond the scope of this class. They do a smoother job of rotations because they deal with an angle and an axis of rotation, rather than 3 angles about the principle axes, which is somewhat arbitrary.

See, for example, [http://en.wikipedia.org/wiki/Quaternion](http://en.wikipedia.org/wiki/Quaternion)
