Some Useful Conversions

1 meter = 39.37 inches = 3.28 feet
1 mile = 1,610 meters = 1.610 kilometers
1 mile per hour = 1.467 feet per second
1 mile per hour = 0.447 meters per second
1 gallon = 3.79 liters
1 cubic foot = 7.48 gallons = 28.35 liters
1 kilogram = 2.2 pounds (mass, at Earth's surface)
1 Newton = 0.224 pounds (force)
1 pound = 4.45 Newtons (force)
1 radian = 57.3°

What's the Difference Between Mass and Weight?

**Mass** is the resistance to acceleration and deceleration. You can also think of it as inertia -- how difficult it is to accelerate a wagon with something in it.

**Weight** is the force pulling you towards the center of whatever planetary body you happen to be standing on.

On the moon, your mass would be the same as it is on Earth. It would still require the same amount of force to push you in a (frictionless) wagon.

On the moon, however, your weight would be about 1/6 of what it is on Earth.

Because most of us are stuck on Earth, within a mile or two of sea level, in common practice, “mass” and “weight” designate about the same thing.

Newton's Three Laws of Motion

1. Every object in motion keeps that same motion (i.e., same speed and direction) unless an external force acts on it.
2. Force equals mass times acceleration (F=ma)
3. For every action, there is an equal and opposite reaction.

Newton's Three Laws of Motion

Newton’s Gravitational Law says that the attraction force between two objects is the product of their masses times the gravitational constant G, divided by the square of the distance between them:

\[ F_{12} = \frac{G m_1 m_2}{d_{12}^2} \]

where: \( G = 6.67 \times 10^{-11} \text{Nm}^2 \text{kg}^{-2} \)

and \( d_{12} \) is the distance between body 1 and body 2

For an object, \( m \), at or near the surface of the Earth (i.e., \( d_{12} \) is the radius of the Earth) this simplifies to:

\[ F = mg \]

where: \( g = -9.8 \text{ meters/second}^2 \approx -32.2 \text{ feet/second}^2 \)

\( g \) is known as the \text{Acceleration Due to (Earth's) Gravity}

Constant-Acceleration Formulas

(These need to be memorized)

\[ v_f = v_i + at \]
\[ d_f = d_i + v_i t + \frac{1}{2} at^2 \]

If you are moving vertically, then the acceleration, \( a \), will be the acceleration due to gravity, \( g \):

\[ d_f = d_i + v_i t + \frac{1}{2} at^2 \]

\[ g = -9.8 \text{ meters/second}^2 \approx -32.2 \text{ feet/second}^2 \]

If you are moving horizontally, there is no acceleration unless some outside horizontal force creates it.

\[ d_f = d_i + v_i t \]

The following formula is handy because it relates all the usual quantities, but doesn’t require you to know the elapsed time:

\[ v_f^2 = v_i^2 + 2a(d_f - d_i) \]

Projectile Motion

\[ \ddot{Y} = V \cos \theta, \dot{Y} \sin \theta \]

Initial Quantities:

\[ X: \quad a_x = 0 \]
\[ Y: \quad a_y = g \]
\[ V_x = V \cos \theta \]
\[ V_y = V \sin \theta \]

Quantities in Flight:

\[ X: \quad \dot{x} = v_x, \quad \ddot{x} = 0 \]
\[ Y: \quad \dot{y} = h_y + v_y t + \frac{1}{2} \frac{g}{2} t^2 \]
A Projectile Launches – Where Does it End Up?

Strategy: Treat each case separately. Figure out what limitation makes the projectile stop moving, calculate the time to get to that, and then see where the projectile would have ended up first.

Case 1. What if it Never Reaches the Cliff?

Y Distance Equation:
\[ y = y_0 + v_{y0} t - \frac{1}{2} g t^2 \]

Solve for the time:
\[ t^* = \frac{v_{y0}}{g} \]

Note: \( g < 0 \).

How Far will it Go?

Solve for the X Distance:
\[ d_x = d_{cliff} + v_{x0} t^* \]

Case 2. What if it Hits the Side of the Cliff?

X Distance Equation:
\[ d_{cliff} = 0 + v_{x0} t^* \]

Solve for the time:
\[ t^* = \frac{d_{cliff}}{v_{x0}} \]

How High will it Go?

Solve for the Y Distance:
\[ h = 0 + v_{y0} t^* - \frac{1}{2} g t^*^2 \]

Case 3. What if it Lands on Top of the Cliff?

Y Distance Equation:
\[ y_{impact} = 0 + v_{y0} t + \frac{1}{2} g t^2 \]

Solve for the time:
\[ t^* = \frac{-v_{y0} \pm \sqrt{v_{y0}^2 + 2gh_{impact}}}{g} \]

Note: \( g < 0 \).

How Far will it Go?

Solve for the X Distance:
\[ d_x = d_{cliff} + v_{x0} t^* \]

How do you decide if Case 1, 2, or 3 is the Correct Solution?

Consider Case #1: If the horizontal distance that it travels is \( \leq d_{cliff} \), then this is what happened.

Consider Case #2: If the height of the projectile is \( \leq h_{cliff} \) as its horizontal distance passes \( d_{cliff} \), then this is what happened.

Otherwise, Case #3 is what happened.
Case 1, 2, 3 Projectile Motion: When and Where will the Projectile Reach its Maximum Height?

- The y velocity at the maximum height is zero.

\[ v_y = v_{y0} + gt = 0 \]

Solve for the time:
\[ t = \frac{-v_{y0}}{g} \]

Note: \( g < 0 \).

How High will It Go?

\[ h = v_{y0}^2 \left( \frac{1}{2} - \frac{1}{2} g t^2 \right) \]

Let's Try it with Some Numbers

Find how much time it takes for the projectile to hit the ground.
Find how far the projectile travels horizontally before hitting the ground.
Find the maximum height the projectile reaches before starting back down.

Simplify \( g \) to be -10 meters/sec^2.

1. Deal with just the Y component first. What is the equation that relates distance travelled to initial velocity and gravitational acceleration?

\[ d_{\text{y}} = d_{\text{y0}} + v_{\text{y0}}t + \frac{1}{2}gt^2 \]

2. Solve for \( t \) when \( d_{\text{y}} = d_{\text{y0}} \). Why are there 2 answers? What are they? Which one do you want?

3. Now deal with the X component. What equation relates distance traveled to initial velocity and gravitational acceleration?

\[ d_{\text{x}} = v_{\text{x}}t \]

4. Plug in the \( v_{\text{x}} \) you got in step #2. How far did the projectile travel?

The Physics of Bouncing Against a Floor or Wall

To treat the case of an object bouncing against an immovable object, such as a floor or a solid wall, the resulting velocity is:

\[ v' = -e v \]

Where \( e \) is the Coefficient of Restitution (CoR), and is a measure of how much energy is retained during the bounce.

The amount of energy actually retained during the collision is:

\[ E_{\text{retained}} = e^2 \]

Which means that:

\[ E_{\text{lost}} = (1 - e^2) \]

Let's Try it with Some Numbers

Find how long until the next bounce?

Find how far the ball travels horizontally before hitting the ground.

Find how much time it takes for the ball to hit the ground.

A Ball Bouncing in a Box

Current Position \((x,y)\)
Current Velocity \((v_x,v_y)\)

How long until the next bounce?

\[ x' = x + v_xt = x_{\text{left}} + \text{radius} \]

\[ y' = y + v_yt + \frac{1}{2}gt^2 = y_{\text{floor}} + \text{radius} \]

1. Figure out which equation produces the minimum positive \( t \) value
2. Advance the ball that much
3. Perform the bounce in the proper direction
4. Handle the rest of the time step: \( v'_y = -ev_y \), \( v'_x = v_x \)

\[ \text{E}_{\text{lost}} = (1 - e^2) \]
The Physics of Bouncing Against a Floor or Wall

So far, we have only been dealing with objects undergoing linear motion

What about objects undergoing rotational motion?

1. Spinning motion
2. Motion around a curve

Motion around a curve:
Centripetal / Centrifugal Force

1. Every object in motion keeps that same motion (i.e., same speed and direction) unless an external force acts on it.
2. Force equals mass times acceleration (F=ma)
3. For every action, there is an equal and opposite reaction.

That force is called Centripetal Force, and acts on all objects as they round curves in order to make them round the curve and not go flying off.

For the car, that force is the friction of the road on the tires. For you, that force is the side of the car on you.

Then What is Centrifugal Force?

The Centripetal Force is making the block change directions. This is what we observe from the outside.

But, if we were observing while riding on the block, the motion direction that our mass wants to keep is the original straight line. But, the block has been forced to change to a new direction. Until our mass also changes to this new direction, we are going to keep trying to go in the old direction, which seems to us to be towards the outside of the curve. We think we are being "thrown" there, but it is just a natural consequence of Newton’s First Law.

Then What is Centrifugal Force?

http://xkcd.com
How Much Force is the Centripetal Force and Where Does it Point?

This force points towards the instantaneous center of curvature.

Torque

Torque is like the rotational-motion equivalent of force. It is defined as a force, $F$, acting at a distance, $d$. (That distance is sometimes called a moment-arm.)

An object is in static equilibrium if:
1. Sum of the forces = 0
2. Sum of the torques = 0

Torque Imbalances

Torque is defined as a force, $F$, acting at a distance, $d$. In the example below, the arm will rotate if $F_1 \times d_1 \neq F_2 \times d_2$.

What are the impacts of $m$, $v$, $R$, $h$, and $w$?
