The OpenGL Mathematics (GLM) Library

GLM is a set of C++ classes and functions to fill in the programming gaps in writing the basic vector and matrix mathematics for OpenGL applications.

GLM isn’t really a library—it is all specified in *.hpp header files so that it gets compiled in with your source code.

You can find it at:
http://glm.g-truc.net/0.9.8.5/

You invoke GLM like this:
#define    GLM_FORCE_RADIANS
#include <glm/glm.hpp>
#include <glm/gtc/matrix_transform.hpp>

Or, you can #include only the specific GLM .hpp files you need.

If GLM is not installed in a system place, put it somewhere you can get access to. Later on, these notes will show you how to use it from there.

Why are we even talking about this?

The OpenGL overlords have “deprecated” some of the OpenGL functions we have been using to perform transformations. In the desktop world, it means that the use of such functions is discouraged. In the mobile world of OpenGL-ES, it means those functions are gone. You might as well become familiar with how to live without them. So, instead of saying:
gluLookAt( 0., 0., 3., 0., 0., 0., 0., 1., 0. );
oglRotate( (GLfloat)Yrot, 0., 1., 0. );
oglRotate( (GLfloat)Xrot, 1., 0., 0. );
oglScalef( (GLfloat)Scale, (GLfloat)Scale, (GLfloat)Scale );

you would say:

glm::mat4 modelview;
glm::vec3 eye(0.,0.,3.);
glm::vec3 look(0.,0.,0.);
glm::vec3 up(0.,1.,0.);
modelview = glm::lookAt( eye, look, up );
modelview = glm::rotate( modelview, D2R*Yrot, glm::vec3(0.,1.,0.) );
modelview = glm::rotate( modelview, D2R*Xrot, glm::vec3(1.,0.,0.) );
modelview = glm::scale( modelview, glm::vec3(Scale,Scale,Scale) );
glMultMatrixf( glm::value_ptr( modelview )   );

Exactly the same concept, but a different expression of it. Read on for details …

The Most Useful GLM Variables, Operations, and Functions

If constructor:
glm::mat4( );
glm::vec4( ); // identity matrix
GLM recommends that you use the “glm::” syntax and not use “using namespace” syntax because they have not made any effort to create unique function names.

If multiplications:
glm::mat4 * glm::mat4
glm::mat4 * glm::vec4
glm::mat4 * glm::vec3
// promote vec3 to a vec4 via a constructor

If emulating OpenGL transformations with concatenation:
glm::mat4 glm::rotate( glm::mat4 const & m, float angle, glm::vec3 const & axis );
glm::mat4 glm::scale( glm::mat4 const & m, glm::vec3 const & factors );
glm::mat4 glm::translate( glm::mat4 const & m, glm::vec3 const & translation );

Installing GLM into your own space

I like to just put the whole thing under my Visual Studio project folder so I can zip up a complete project and give it to someone else.
Here’s what that GLM folder looks like

Telling Linux about where the GLM folder is

```bash
g++ … -I ...
```

“minus-capital-eye-period” means “also look for the < > includes in this same folder”

Instead of the period, you can list a full or relative pathname.

Telling Visual Studio about where the GLM folder is

1. 
2. 

A period, indicating that the project folder should also be searched when a `#include <xxx>` is encountered. If you put it somewhere else, enter that full or relative path instead.

Using Transformations OpenGL-style, like in the sample.cpp pProgram

```cpp
gMatrixMode( GL_PROJECTION );
gLoadIdentity( );
if( WhichProjection == ORTHO )
gOrtho(-3., 3., -3., 3., 0.1, 1000.);
else
gluPerspective( 90., 1., 0.1, 1000. );
// place the objects into the scene:
gMatrixMode( GL_MODELVIEW );
gLoadIdentity( );
// set the eye position, look-at position, and up-vector:
gluLookAt( 0., 0., 3., 0., 0., 0., 0., 1., 0. );
// rotate the scene:
gRotatef( (GLfloat)Yrot, 0., 1., 0. );
gRotatef( (GLfloat)Xrot, 1., 0., 0. );
// uniformly scale the scene:
if( Scale < MINSCALE )
Scale = MINSCALE;
gScalef( (GLfloat)Scale, (GLfloat)Scale, (GLfloat)Scale );
```
// place the objects into the scene:
glMatrixMode( GL_MODELVIEW );
glLoadIdentity( );

// set the eye position, look-at position, and up-vector:
glm::vec3 eye(0.,0.,3.);
glm::vec3 look(0.,0.,0.);
glm::mat4 modelview = glm::lookAt( eye, look, up );

// rotate the scene (warning -- unlike OpenGL’s glRotatef,
// GLM’s rotate method takes angles in “radians”):
modelview = glm::rotate( modelview, D2R*Yrot, glm::vec3(0.,1.,0.) );
modelview = glm::rotate( modelview, D2R*Xrot, glm::vec3(1.,0.,0.) );

// uniformly scale the scene:
if( Scale < MINSCALE )
  Scale = MINSCALE;
modelview = glm::scale( modelview, glm::vec3(Scale,Scale,Scale) );

// apply the modelview matrix:
glMultMatrixf( glm::value_ptr( modelview ) );

// set the view matrix:
glm::vec3 eye (0.,0.,3.);
glm::vec3 look (0.,0.,0.);
glm::vec3 up (0.,1.,0.);
glm::mat4 view = glm::lookAt ( eye, look, up );
glm::mat4 model = glm::rotate ( modelview, D2R*Yrot, glm::vec3(0.,1.,0.) );
glm::mat4 model = glm::rotate ( modelview, D2R*Xrot, glm::vec3(1.,0.,0.) );
glm::mat4 projection = glm::perspective ( D2R*90., 1., 0.1, 1000. );
projection[1][1] *= -1.; // Vulkan’s projected Y is inverted from OpenGL
