The Basic Computer Graphics Pipeline

We'll come back to this later. For now, understand that there are multiple steps to go from your 3D geometry to pixels on the screen.

MC = Model Coordinates
WC = World Coordinates
EC = Eye Coordinates
CC = Clip Coordinates
NDC = Normalized Device Coordinates
SC = Screen Coordinates
Geometry vs. Topology

**Geometry:**
Where things are (e.g., coordinates)

**Topology:**
How things are connected

Original Object

Geometry = changed
Topology = same (1-2-3-4-1)

Geometry = same
Topology = changed (1-2-4-3-1)
3D Coordinate Systems

Left-handed

Right-handed
Since Homer Simpson uses Right-handed Coordinates, then we will too
Right-handed 3D Coordinate System for a CNC Machine
Right-handed Positive Rotations

Right-Handed Coordinate System
Drawing in 3D

```c
setColor3f( r, g, b );

begin( GL_LINE_STRIP);
    glVertex3f( x0, y0, z0);
    glVertex3f( x1, y1, z1);
    glVertex3f( x2, y2, z2);
    glVertex3f( x3, y3, z3);
    glVertex3f( x4, y4, z4);
end();
```

Set any display-characteristics state that you want to have in effect when you do the drawing.

Begin the drawing. Use the current state’s display-characteristics. Here is the topology to be used with these vertices.

This is a wonderfully understandable way to start with 3D graphics, but it is also incredibly inefficient! We’ll talk about that later…
OpenGL Topologies

OpenGL Topologies

GL_TRIANGLE_FAN

GL_QUAD_STRIP

GL_QUADS

GL_POLYGON
OpenGL Topologies – Polygon Requirements

Polygons must be:

- **Convex** and
- **Planar**

For that reason, GL_TRIANGLES_STRIP and GL_TRIANGLES are considered preferable to GL_QUAD_STRIP and GL_QUADS. GL_POLYGON is rarely used.
OpenGL Topologies -- Orientation

Polygons are traditionally:

- **CCW when viewed from outside the solid object**

It doesn’t matter much, but there is an advantage in being **consistent**
OpenGL Topologies – Vertex Order Matters

GL_LINE_LOOP

V₀

V₃

V₀
V₁
V₂
V₃

Probably what you meant to do

Probably not what you meant to do

This disease is referred to as “The Bowtie” 😊
What does “Convex Polygon” Mean?

We can go all mathematical here, but let’s go visual instead. In a convex polygon, a line between any two points inside the polygon never leaves the inside of the polygon.

**Convex**

Stays within the polygon

**Not Convex**

Leaves the polygon
Why is there a Requirement for Polygons to be Convex?

Graphics polygon-filling hardware can be highly optimized if you know that, no matter what direction you fill the polygon in, there will be two and only two intersections between the scanline and the polygon’s edges.

Convex

Not Convex

2 edge intersections

4 edge intersections
What if you need to display Polygons that are not Convex?

There are two good solutions I know of (and there are probably more):

1. OpenGL’s utility (gluXxx) library has a built-in tessellation capability to break a non-convex polygon into convex polygons.

2. There is an open source library to break a non-convex polygon into convex polygons. It is called Polypartition, and the source code can be found here:

   https://github.com/ivanfratric/polypartition

If you ever need to do this, contact me. I have working code for each approach…
Why is there a Requirement for Polygons to be Planar?

Graphics hardware assumes that a polygon has a definite front and a definite back, and that you can only see one of them at a time.
OpenGL Drawing Can Be Done Procedurally

```c
glColor3f( r, g, b );
glBegin( GL_LINE_LOOP );
    glVertex3f( x0, y0, 0. );
    glVertex3f( x1, y1, 0. );
    ... 
    glEnd( );
```

Listing a lot of vertices explicitly gets old in a hurry

```
    glColor3f( r, g, b );
    float dang = 2. * M_PI / (float)( NUMSEGS – 1 );
    float ang = 0.;
    glBegin( GL_LINE_LOOP );
        for( int i = 0; i < NUMSEGS; i++ )
            {
            glVertex3f( RADIUS*cos(ang),  RADIUS*sin(ang),  0. );
            ang += dang;
            }
    glEnd( );
```

The graphics card can't tell how the numbers in the glVertex3f calls were produced: both explicitly listed and procedurally computed look the same to glVertex3f.
glColor3f( r, g, b );

0.0 ≤ r, g, b ≤ 1.0

This is referred to as "Additive Color"

Cyan = Green + Blue
Magenta = Red + Blue
Yellow = Red + Green
White = Red + Green + Blue
Transformations

Translation

Rotation

Scaling
OpenGL Transformations

```c
glTranslatef( tx, ty, tz );
```

```c
glRotatef( degrees, ax, ay, az );
```

```c
glScalef( sx, sy, sz );
```
Single Transformations

```c
glMatrixMode( GL_MODELVIEW );
glLoadIdentity( )

glRotatef( degrees, ax, ay, az );

glColor3f( r, g, b );
glBegin( GL_LINE_STRIP );
    glVertex3f( x0, y0, z0 );
    glVertex3f( x1, y1, z1 );
    glVertex3f( x2, y2, z2 );
    glVertex3f( x3, y3, z3 );
    glVertex3f( x4, y4, z4 );
glEnd( );
```
Compound Transformations

glMatrixMode( GL_MODELVIEW );
glLoadIdentity( );

1. glTranslatef( tx, ty, tz );
2. glRotatef( degrees, ax, ay, az );
3. glScalef( sx, sy, sz );

1. glColor3f( r, g, b );
glBegin( GL_LINE_STRIP );
   glVertex3f( x0, y0, z0 );
   glVertex3f( x1, y1, z1 );
   glVertex3f( x2, y2, z2 );
   glVertex3f( x3, y3, z3 );
   glVertex3f( x4, y4, z4 );
glEnd( );

These transformations “add up”, and look like they take effect in this order.
Why do the Compound Transformations Take Effect in Reverse Order?

Envision fully-parenthesizing what is going on. In that case, it makes perfect sense that the most recently-set transformation would take effect first.
Order Matters!
Compound Transformations are Not Commutative
The OpenGL Drawing State

The designers of OpenGL could have put lots and lots of arguments on the glVertex3f call to totally define the appearance of your drawing, like this:

```c
glVertex3f( x, y, z,  r, g, b,  m00, ..., m33,  s, t,  nx, ny, nz,  linewidth, ... );
```

Yuch! *That* would have been ugly. Instead, they decided to let you create a “current drawing state”. You set all of these characteristics first, then they take effect when you do the drawing. They continue to remain in effect for future drawing calls, until you change them.

You must set the transformations before you expect them to take effect!

Set the state first

```
glMatrixMode( GL_MODELVIEW );
glLoadIdentity();
```

```
GLfloat translate(tx, ty, tz);
```

```
GLfloat rotate_degrees, ax, ay, az;
```

```
GLfloat scale(sx, sy, sz);
```

```
GLfloat color(r, g, b);
```

```
void begin(GLenum mode);
```

```
void vert豸(x, y, z);
```

```
void vert豸(x1, y1, z1);
```

```
void vert豸(x2, y2, z2);
```

```
void vert豸(x3, y3, z3);
```

```
void vert豸(x4, y4, z4);
```

Use the state second

```c
void end();
```
Projecting an Object from 3D into 2D

Orthographic (or Parallel) projection

\texttt{glOrtho( \textit{xl}, \textit{xr}, \textit{yb}, \textit{yt}, \textit{zn}, \textit{zf});}

Perspective projection

\texttt{gluPerspective( \textit{fovy}, \textit{aspect}, \textit{zn}, \textit{zf});}
Projecting on Object from 3D to 2D

Parallel/Orthographic is good for lining things up and comparing sizes

Perspective is more realistic-looking
OpenGL Projection Functions

```c
#include <glut.h>

// Set the projection matrix
glMatrixMode( GL_PROJECTION );
glLoadIdentity( );

// Set the modelview matrix
glMatrixMode( GL_MODELVIEW );
glLoadIdentity( );

// Set the clipping volume
glOrtho( xl, xr, yb, yt, zn, zf );
gluPerspective( fovy, aspect, zn, zf );
```

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>glMatrixMode(GL_PROJECTION)</code></td>
<td>Set the projection matrix</td>
</tr>
<tr>
<td><code>glMatrixMode(GL_MODELVIEW)</code></td>
<td>Set the modelview matrix</td>
</tr>
<tr>
<td><code>glLoadIdentity()</code></td>
<td>Reset the matrix to identity</td>
</tr>
<tr>
<td><code>glOrtho()</code></td>
<td>Set the clipping volume</td>
</tr>
<tr>
<td><code>gluPerspective()</code></td>
<td>Set the perspective parameters</td>
</tr>
</tbody>
</table>

Use one of these, but not both!
How the Viewing Volumes Look from the Outside

\[
\text{glOrtho}( \ x_l, \ x_r, \ y_b, \ y_t, \ z_n, \ z_f );
\]

\[
\text{gluPerspective}( \ \text{fovy}, \ \text{aspect}, \ z_n, \ z_f );
\]
The Perspective Viewing Frustum

\texttt{gluPerspective( fovy, aspect, \ zn, \ zf );}

\textit{fovy} = vertical field of view angle (degrees)
(good values are 50-100°)

\textit{aspect} = DX/DY

\texttt{DX}
\texttt{DY}
\texttt{znear}
\texttt{zfar}
Arbitrary Viewing

```c
glMatrixMode( GL_PROJECTION );
glLoadIdentity( );
gluPerspective( fpvy, aspect, zn, zf );

glMatrixMode( GL_MODELVIEW );
glLoadIdentity( );
gluLookAt( ex, ey, ez, lx, ly, lz, ux, uy, uz );
glTranslatef( tx, ty, tz );
glRotatef( degrees, ax, ay, az );
glScalef( sx, sy, sz );
glColor3f( r, g, b );
glBegin( GL_LINE_STRIP );
glVertex3f( x0, y0, z0 );
glVertex3f( x1, y1, z1 );
glVertex3f( x2, y2, z2 );
glVertex3f( x3, y3, z3 );
glVertex3f( x4, y4, z4 );
glEnd( );
```
Chicago Fly-through: Changing Eye, Look, and Up
How Can You Be Sure You See Your Scene?

```c
void gluPerspective( fovy, aspect, zn, zf);

void gluLookAt( ex, ey, ez, lx, ly, lz, ux, uy, uz);
```

Here’s a good way to start:

1. Set \( lx, ly, lz \) to be the average of all the vertices.
2. Set \( ux, uy, uz \) to be \( 0., 1., 0. \).
3. Set \( ex=lx \) and \( ey=ly \).
4. Now, you change \( \Delta E \) or \( fovy \) so that the object fits in the viewing volume:

\[
\tan\left(\frac{fovy}{2}\right) = \frac{H/2}{\Delta E}
\]

Giving:

\[ fovy = 2 \arctan\left(\frac{H}{2\Delta E}\right) \]

or:

\[ \Delta E = \frac{H}{2 \tan\left(\frac{fovy}{2}\right)} \]
Specifying a Viewport

Be sure the y:x aspect ratios match!!

```c
glViewport( ixl, iyb, idx, idy );

glMatrixMode( GL_PROJECTION );
gluPerspective( fovy, aspect, zn, zf );

glMatrixMode( GL_MODELVIEW );
gluLookAt( ex, ey, ez, lx, ly, lz, ux, uy, uz );
glTranslatef( tx, ty, tz );
glRotatef( degrees, ax, ay, az );
glScalef( sx, sy, sz );

glColor3f( r, g, b );
glBegin( GL_LINE_STRIP );
glVertex3f( x0, y0, z0 );
glVertex3f( x1, y1, z1 );
glVertex3f( x2, y2, z2 );
glVertex3f( x3, y3, z3 );
glVertex3f( x4, y4, z4 );
glEnd( );
```

Viewports use the upper-left corner as (0,0) and their Y goes down

Note: setting the viewport is not part of setting either the Modelview or the Projection transformations.
Saving and Restoring the Current Transformation

glViewport( ixl, iyb, idx, idy );

glMatrixMode( GL_PROJECTION );
glLoadIdentity( );
gluPerspective( fovy, aspect, zn, zf );

glMatrixMode( GL_MODELVIEW );
glLoadIdentity( );
gluLookAt( ex, ey, ez, lx, ly, lz, ux, uy, uz );
glTranslatef( tx, ty, tz );

**glPushMatrix( );**

**glPushMatrix( );**

glTranslatef( tx, ty, tz );
glRotatef( degrees, ax, ay, az );
glScalef( sx, sy, sz );

glColor3f( r, g, b );
glBegin( GL_LINE_STRIP );
glVertex3f( x0, y0, z0 );
glVertex3f( x1, y1, z1 );
glVertex3f( x2, y2, z2 );
glVertex3f( x3, y3, z3 );
glVertex3f( x4, y4, z4 );

**glEnd( );**

**glPopMatrix( );**

Sidebar: How Did We Make the Transition from Vertices to Pixels?

There is a piece of hardware called the **Rasterizer**. Its job is to interpolate a line or polygon, defined by vertices, into a collection of **fragments**. Think of it as filling in squares on graph paper.

A fragment is a “pixel-to-be”. In computer graphics, “pixel” is defined as having its full RGBA already computed. A fragment does not yet but all of the information needed to compute the RGBA is there.

A fragment is turned into a pixel by the **fragment processing** operation.

In CS 457/557, you will do some pretty snazzy things with your own fragment processing code!
