The Basic Computer Graphics Pipeline

We’ll come back to this later. For now, understand that there are multiple steps to go from your 3D vertex geometry to pixels on the screen.

MC = Model Coordinates
WC = World Coordinates
EC = Eye Coordinates
CC = Clip Coordinates
NDC = Normalized Device Coordinates
SC = Screen Coordinates
**Geometry vs. Topology**

**Geometry:**
Where things are (e.g., coordinates)

**Topology:**
How things are connected

Original Object

Geometry = changed
Topology = same (1-2-3-4-1)

Geometry = same
Topology = changed (1-2-4-3-1)
3D Coordinate Systems

Left-handed

Right-handed
Homer Simpson uses Right-handed Coordinates. So, we will too.
Right-handed 3D Coordinate System for a CNC Machine
Right-handed Positive Rotations

Right-Handed Coordinate System
```c
void drawIn3D(float x0, float y0, float z0, float x1, float y1, float z1, float x2, float y2, float z2, float x3, float y3, float z3, float x4, float y4, float z4)
{
    glColor3f(r, g, b);
    glBegin(GL_LINE_STRIP);
    glVertex3f(x0, y0, z0);
    glVertex3f(x1, y1, z1);
    glVertex3f(x2, y2, z2);
    glVertex3f(x3, y3, z3);
    glVertex3f(x4, y4, z4);
    glEnd();
}
```

This is a wonderfully understandable way to start with 3D graphics – it is like holding a marker in your hand and sweeping out linework in the 3D air in front of you! But it is also incredibly internally inefficient! We’ll talk about that later and what to do about it…
OpenGL Topologies

GL_POINTS

GL_LINES

GL_LINE_STRIP

GL_LINE_LOOP

GL_TRIANGLES

GL_TRIANGLE_STRIP
OpenGL Topologies

**GL_TRIANGLE_FAN**

- V0
- V1
- V2

- V3
- V4
- V5
- V6
- V7
OpenGL Topologies – Polygon Requirements

Polygons must be:

- **Convex** and
- **Planar**

GL_TRIANGLES and GL_TRIANGLES are considered to be preferable to GL_QUAD_STRIP and GL_QUADS. GL_POLYGON is rarely used.
OpenGL Topologies -- Orientation

Polygons are traditionally:

- **CCW when viewed from outside the solid object**

It doesn’t matter much, but there is an advantage in being *consistent*.
OpenGL Topologies – Vertex Order Matters

GL_LINE_LOOP

```
V0  V3
  ^
  |
V1  V2
```

Probably what you meant to do

GL_LINE_LOOP

```
V0  V2
  |
  V1
```

Probably not what you meant to do

This disease is referred to as “The Bowtie” 😊
What does “Convex Polygon” Mean?

We can go all mathematical here, but let’s go visual instead. In a convex polygon, a line between any two points inside the polygon never leaves the inside of the polygon.

Convex

Stays within the polygon

Not Convex

Leaves the polygon
Why is there a Requirement for Polygons to be Convex?

Graphics polygon-filling hardware can be highly optimized if you know that, no matter what direction you fill the polygon in, there will be two and only two intersections between the scanline and the polygon’s edges.
What if you need to display Polygons that are not Convex?

There are two good solutions I know of (and there are probably more):

1. OpenGL’s utility (gluXxx) library has a built-in tessellation capability to break a non-convex polygon into convex polygons.

2. There is an open source library to break a non-convex polygon into convex polygons. It is called Polypartition, and the source code can be found here:

https://github.com/ivanfratric/polypartition

If you ever need to do this, contact me. I have working code for each approach…
Why is there a Requirement for Polygons to be Planar?

Graphics hardware assumes that a polygon has a definite front and a definite back, and that you can only see one of them at a time.
OpenGL Drawing Can Be Done Procedurally

```c
void circle(float RADIUS, float NUMSEGS)
{
    float dang = 2. * M_PI / (float)( NUMSEGS - 1 );
    float ang = 0.;
    glBegin( GL_LINE_LOOP );
    for( int i = 0; i < NUMSEGS; i++ )
    {
        glVertex3f( RADIUS*cos(ang), RADIUS*sin(ang), 0. );
        ang += dang;
    }
    glEnd( );
}
```

Listing a lot of vertices explicitly gets old in a hurry.

The graphics card can’t tell how the numbers in the glVertex3f calls were produced: both explicitly listed and procedurally computed look the same to glVertex3f.
Color

```
glColor3f( r, g, b );
```

This is referred to as “Additive Color”

Cyan = Green + Blue
Magenta = Red + Blue
Yellow = Red + Green
White = Red + Green + Blue
Transformations

Translation

Rotation

Scaling
OpenGL Transformations

\begin{align*}
\text{glTranslatef( } & \text{tx, ty, tz);} \\
\text{glRotatef( } & \text{degrees, ax, ay, az);} \\
\text{glScalef( } & \text{sx, sy, sz);} \\
\end{align*}
Single Transformations

glMatrixMode( GL_MODELVIEW );
glLoadIdentity( )

glTranslatef( degrees, ax, ay, az );

glColor3f( r, g, b );
glBegin( GL_LINE_STRIP );
    glVertex3f( x0, y0, z0 );
    glVertex3f( x1, y1, z1 );
    glVertex3f( x2, y2, z2 );
    glVertex3f( x3, y3, z3 );
    glVertex3f( x4, y4, z4 );
glEnd( );
Compound Transformations

```
glMatrixMode( GL_MODELVIEW );
glLoadIdentity( )

glTranslatef( tx, ty, tz );
glRotatef( degrees, ax, ay, az );
glScalef( sx, sy, sz );
```

```
glColor3f( r, g, b );
gBegin( GL_LINE_STRIP );
  glVertex3f( x0, y0, z0 );
  glVertex3f( x1, y1, z1 );
  glVertex3f( x2, y2, z2 );
  glVertex3f( x3, y3, z3 );
  glVertex3f( x4, y4, z4 );
gEnd( );
```

These transformations “add up”, and look like they take effect in this order.

1. glMatrixMode
2. glLoadIdentity
3. glTranslatef
4. glRotatef
5. glScalef

Oregon State University
Computer Graphics

mjb – July 13, 2020
Why do the Compound Transformations Take Effect in Reverse Order?

Envision fully-parenthesizing what is going on. In that case, it makes perfect sense that the most recently-set transformation would take effect first.
Order Matters!
Compound Transformations are Not Commutative

Rotate, then translate

Translate, then rotate
The OpenGL Drawing State

The designers of OpenGL could have put lots and lots of arguments on the glVertex3f call to totally define the appearance of your drawing, like this:

```c
glVertex3f( x, y, z,  r, g, b,  m00, …, m33,  s, t,  nx, ny, nz,  linewidth, …  );
```

Yuch! *That* would have been ugly. Instead, they decided to let you create a “current drawing state”. You set all of these characteristics first, then they take effect when you do the drawing. They continue to remain in effect for future drawing calls, until you change them.

```
glMatrixMode( GL_MODELVIEW );
glLoadIdentity( );

glTranslatef( tx, ty, tz );
glRotatef( degrees, ax, ay, az );
glScalef( sx, sy, sz );

glColor3f( r, g, b );
glBegin( GL_LINE_STRIP );
  glVertex3f( x0, y0, z0 );
  glVertex3f( x1, y1, z1 );
  glVertex3f( x2, y2, z2 );
  glVertex3f( x3, y3, z3 );
  glVertex3f( x4, y4, z4 );
  glEnd( );
```

You must set the transformations before you expect them to take effect!

Set the state first

Draw with the state second
Projecting an Object from 3D into 2D

**Orthographic (or Parallel) projection**

```c
glOrtho( xl, xr, yb, yt, zn, zf );
```

**Perspective projection**

```c
gluPerspective( fovy, aspect, zn, zf );
```

Parallel lines remain parallel

Parallel lines appear to converge

“Vanishing Point”
Projecting on Object from 3D to 2D

Parallel/Orthographic is good for lining things up and comparing sizes

Perspective is more realistic-looking
OpenGL Projection Functions

```c
glMatrixMode( GL_PROJECTION );
glLoadIdentity( );

Use one of these, but not both!

Use one of these, but not both!

glOrtho( xl, xr, yb, yt, zn, zf );
gluPerspective( fovy, aspect, zn, zf );

glMatrixMode( GL_MODELVIEW );
gLoadIdentity( );

gluLookAt( ex, ey, ez, lx, ly, lz, ux, uy, uz );

glTranslatef( tx, ty, tz );
glRotatef( degrees, ax, ay, az );
glScalef( sx, sy, sz );

glColor3f( r, g, b );
gBegin( GL_LINE_STRIP );
glVertex3f( x0, y0, z0 );
glVertex3f( x1, y1, z1 );
glVertex3f( x2, y2, z2 );
glVertex3f( x3, y3, z3 );
glVertex3f( x4, y4, z4 );
gEnd( );
```
How the Viewing Volumes Look from the Outside

\[ \text{glOrtho}( \text{xl}, \text{xr}, \text{yb}, \text{yt}, \text{zn}, \text{zf}); \quad \text{gluPerspective}( \text{fovy}, \text{aspect}, \text{zn}, \text{zf}); \]

Parallel/Orthographic

Perspective
The Perspective Viewing Frustum

gluPerspective( fovy, aspect, znear, zfar );

fovy = vertical field of view angle (degrees)
    (good values are 50-100°)

aspect = DX/DY
Arbitrary Viewing

```c
glMatrixMode( GL_PROJECTION );
glLoadIdentity();
gluPerspective( fovy, aspect, zn, zf );

glMatrixMode( GL_MODELVIEW );
glLoadIdentity();

    // Eye Position Look-at Position Up vector
    gluLookAt( ex, ey, ez, lx, ly, lz, ux, uy, uz );

glTranslatef( tx, ty, tz );
glRotatef( degrees, ax, ay, az );
glScalef( sx, sy, sz );

glColor3f( r, g, b );
glBegin( GL_LINE_STRIP );
    glVertex3f( x0, y0, z0 );
    glVertex3f( x1, y1, z1 );
    glVertex3f( x2, y2, z2 );
    glVertex3f( x3, y3, z3 );
    glVertex3f( x4, y4, z4 );
glEnd( );
```
Chicago Fly-through: Changing Eye, Look, and Up

Skidmore, Owings, and Merrill
How Can You Be Sure You See Your Scene?

```c
gluPerspective( fovy, aspect, zn, zf );
```

```c
gluLookAt( ex, ey, ez, lx, ly, lz, ux, uy, uz );
```

Here's a good way to start:

1. Set \( lx,ly,lz \) to be the average of all the vertices
2. Set \( ux,uy,uz \) to be 0.,1.,0.
3. Set \( ex=lx \) and \( ey=ly \)
4. Now, you change \( \Delta E \) or \( fovy \) so that the object fits in the viewing volume:

\[
tan\left(\frac{fovy}{2}\right) = \frac{H/2}{\Delta E}
\]

Giving:

\[
fovy = 2arctan\left[\frac{H}{2\Delta E}\right]
\]

or:

\[
\Delta E = \frac{H}{2tan\left(\frac{fovy}{2}\right)}
\]
Specifying a Viewport

Be sure the y:x aspect ratios match!!

```
glViewport( ixl, iyb, idx, idy );

glMatrixMode( GL_PROJECTION );
gluPerspective( fovy, aspect, zn, zf );

glMatrixMode( GL_MODELVIEW );
gluLookAt( ex, ey, ez, lx, ly, lz, ux, uy, uz );
glTranslatef( tx, ty, tz );
glRotatef( degrees, ax, ay, az );
glScalef( sx, sy, sz );

glColor3f( r, g, b );
glBegin( GL_LINE_STRIP );
  glVertex3f( x0, y0, z0 );
  glVertex3f( x1, y1, z1 );
  glVertex3f( x2, y2, z2 );
  glVertex3f( x3, y3, z3 );
  glVertex3f( x4, y4, z4 );
glEnd( );
```

Viewports use the upper-left corner as (0,0) and their Y goes down.

Note: setting the viewport is not part of setting either the Modelview or the Projection transformations.
Saving and Restoring the Current Transformation

```c
glViewport( ixl, iyb, idx, idy );

glMatrixMode( GL_PROJECTION );
glLoadIdentity( );
gluPerspective( fovy, aspect, zn, zf );

glMatrixMode( GL_MODELVIEW );
glLoadIdentity( );
gluLookAt( ex, ey, ez, lx, ly, lz, ux, uy, uz );
glTranslatef( tx, ty, tz );
glPushMatrix( );
glPushMatrix( );
glRotatef( degrees, ax, ay, az );
glScalef( sx, sy, sz );

glColor3f( r, g, b );
gBegin( GL_LINE_STRIP );
    glVertex3f( x0, y0, z0 );
    glVertex3f( x1, y1, z1 );
    glVertex3f( x2, y2, z2 );
    glVertex3f( x3, y3, z3 );
    glVertex3f( x4, y4, z4 );
gEnd( );
glPopMatrix( );
glPopMatrix( );

```
sample.cpp Program Structure

- #includes
- Consts and #defines
- Global variables
- Function prototypes
- Main program
- InitGraphics function
- Display callback
- Keyboard callback
```c
#include <stdio.h>
#include <stdlib.h>
#include <ctype.h>
#define _USE_MATH_DEFINES
#include <math.h>

#ifdef WIN32
#include <windows.h>
#pragma warning(disable:4996)
#include "glew.h"
#endif

#include <GL/gl.h>
#include <GL/glu.h>
#include "glut.h"
```
consts and #defines

const char *WINDOWTITLE = { "OpenGL / GLUT Sample -- Joe Graphics" };
const char *GLUITITLE   = { "User Interface Window" };
const int GLUITRUE   = { true  };
const int GLUIFALSE  = { false };
#define ESCAPE          0x1b
const int INIT_WINDOW_SIZE = { 600 };
const float BOXSIZE = { 2.0f };
const float ANGFACT = { 1.0f };
const float SCLFACT = { 0.005f };
const float MINSCALE = { 0.05f };
const int LEFT   = { 4 };
const int MIDDLE = { 2 };
const int RIGHT  = { 1 };
enum Projections

Sidebar: How Did We Make the Transition from Vertices to Pixels?

There is a piece of hardware called the **Rasterizer**. Its job is to interpolate a line or polygon, defined by vertices, into a collection of **fragments**. Think of it as filling in squares on graph paper.

A fragment is a “pixel-to-be”. In computer graphics, the word “pixel” is defined as having its full RGBA already computed. A fragment does not yet have its final RGBA computed, but all of the information needed to compute the RGBA is available to it.

A fragment is turned into a pixel by the **fragment processing** operation.

In CS 457/557, you will do some pretty snazzy things with your own fragment processing code!
