GLSL Geometry Shaders

Here's What We Know So Far

- Fixed Function
- Programmable
Here's What We Know So Far

One Vertex In

\[ \text{Vertex Shader} \]

One Vertex Out

Here's What We Have Next

One Vertex In

\[ \text{Vertex Shader} \]

\[ \text{Primitive Assembly} \]

Array of Vertices Out

\[ \text{Geometry Shader} \]

\[ \text{Primitive Assembly} \]

Arrays of Vertices Out, Possibly with a Change of Topology

\( \text{Fixed Function} \)

\( \text{Programmable} \)
The Geometry Shader: Where Does it Fit in the Pipeline?

- **Fixed Function**
- **Programmable**

If in use, it is always the last stop before the Rasterizer.

Geometry Shader: What Does it Do?

Your application generates these:

The driver translates them into one of these and feeds them one-at-a-time into the Geometry Shader:
- Point, Line, Line with Adjacency, Triangle, Triangle with Adjacency.

The Geometry Shader generates (almost) as many of these as it wants:
- Points, Line Strips, Triangle Strips.

There needn’t be any correlation between Geometry Shader input type and Geometry Shader output type. Points can generate triangles, triangles can generate triangle strips, points can generate points, etc.
Additional Topologies that Geometry Shaders made Available:

- GL_LINES_ADJACENCY
- GL_LINE_STRIP_ADJACENCY
- GL_TRIANGLES_ADJACENCY
- GL_TRIANGLE_STRIP_ADJACENCY

Adjacency Primitives (and what they do when not using shaders)

This is what Fixed-Function OpenGL expects these topologies to mean. In Shader World, they can mean whatever you want them to mean. In Shader World, it's just a way to get some number of vertices into a Geometry Shader.

### Lines with Adjacency

4N vertices are given. (where N is the number of line segments to draw). A line segment is drawn between #1 and #2. Vertices #0 and #3 are there to provide adjacency information.

### Line Strip with Adjacency

N+3 vertices are given (where N is the number of line segments to draw). A line segment is drawn between #1 and #2, #2 and #3, ..., #N and #N+1. Vertices #0 and #N+2 are there to provide adjacency information.
Adjacency Primitives (and what they do when not using shaders)

**Triangles with Adjacency**

6N vertices are given (where N is the number of triangles to draw). Points 0, 2, and 4 define the triangle. Points 1, 3, and 5 tell where adjacent triangles are.

**Triangle Strip with Adjacency**

4+2N vertices are given (where N is the number of triangles to draw). Points 0, 2, 4, 6, 8, 10, ... define the triangles. Points 1, 3, 5, 7, 9, 11, ... tell where adjacent triangles are.

Adjacency Primitives (and what they do when you are using shaders)

In general, we will use the "with adjacency" primitives as a way of importing some number of vertices into the geometry shader.

These are the most useful:

- **GL_LINES_ADJACENCY** 4 vertices
- **GL_TRIANGLES_ADJACENCY** 6 vertices
What Do the Inputs to a Geometry Shader Look Like?

- **gl_Position**
- **gl_PointSize**
- Plus, any of your own variables that you have declared as `out`

When the Geometry Shader calls **`EmitVertex()`**, this set of variables is copied to an entry in the shader's Primitive Assembly step.

When the Geometry Shader calls **`EndPrimitive()`**, the vertices that have been saved in the Primitive Assembly elements are then assembled, rasterized, etc.

Note: there is no "BeginPrimitive()" function. It is implied by (1) the start of the Geometry Shader, or (2) returning from the `EndPrimitive()` call. Also, there is no need to call `EndPrimitive()` at the end of the Geometry Shader – it is implied.
If you are using a Geometry Shader, then the GS must be used if you want to pass information from the Vertex Shader to the Fragment Shader.

```
out vec4 gl_Position;
out vec4 vColor;
vColor = gl_Color;

These are already declared for you
```

```
in vec4 gl_PositionIn[3];
in vec4 vColor[3];
```

```
in vec4 gl_Position;
in vec4 gColor;
gColor = vColor[k];
```

```
in vec4 gColor;
```

---

Example: A Bézier Curve

\[ P(u) = (1-u)^3P_0 + 3u(1-u)^2P_1 + 3u^2(1-u)P_2 + u^3P_3 \]

Need to pass 4 points in to define the curve. You need to pass N points out to draw the curve as a Line Strip.
Example: Expanding 4 Points into a Bezier Curve with a Variable Number of Line Segments

beziercurve.glib

```
Vertex beziercurve.vert
Geometry beziercurve.geom
Fragment beziercurve.frag
Program BezierCurve uNum <2 4 50>
LineWidth 3.
LinesAdjacency [0. 0. 0.] [1. 1. 1.] [2. 1. 2.] [3. -1. 0.]
```

beziercurve.vert

```
void main( )
{
    gl_Position = gl_ModelViewProjectionMatrix * gl_Vertex;
}
```

beziercurve.frag

```
void main( )
{
    gl_FragColor = vec4( 0., 1., 0., 1.);
}
```

beziercurve.geom

```
#version 330 compatibility
#extension GL_EXT_gpu_shader4: enable
#extension GL_EXT_geometry_shader4: enable
layout( lines_adjacency )  in;
layout( line_strip, max_vertices=200 )  out;
uniform int uNum;
void
main( )
{
    float dt = 1. / float(uNum);
    float t = 0.;
    for( int i = 0; i <= uNum; i++ )
    {
        float omt = 1. - t;
        float omt2 = omt * omt;
        float omt3 = omt * omt2;
        float t2 = t * t;
        float t3 = t2 * t;
        vec4 xyzw = omt3 * gl_PositionIn[0].xyzw +
            3. * t * omt2 * gl_PositionIn[1].xyzw +
            3. * t2 * omt * gl_PositionIn[2].xyzw +
            t3 * gl_PositionIn[3].xyzw;
        gl_Position = xyzw;
        EmitVertex( )
        t += dt;
    }
}
```

Note: layout directives are a GLSL-ism and are used to define what the storage looks like.
Example: Expanding 4 Points into a Bezier Curve with a Variable Number of Line Segments

![Bezier Curve Illustration]

Note: It would have made no Difference if the Matrix Transform had been done in the Geometry Shader instead

**beziercurve.vert**

```glsl
void main()
{
    gl_Position = gl_Vertex;
}
```

**beziercurve.geom**

```glsl
vec4 xyzw = omt3 * gl_PositionIn[0].xyzw + 3.0 * t * omt2 * gl_PositionIn[1].xyzw + 3.0 * t2 * omt * gl_PositionIn[2].xyzw + t3 * gl_PositionIn[3].xyzw;

gl_Position = gl_ModelViewProjectionMatrix * xyzw;
EmitVertex()
}
```
Another Example: Shrinking Triangles

Example: Shrinking Triangles

\[
CG = \left( P_0 + P_1 + P_2 \right) / 3; \\
P_0' = CG + u\text{Shrink} \times (P_0 - CG) \\
P_1' = CG + u\text{Shrink} \times (P_1 - CG) \\
P_2' = CG + u\text{Shrink} \times (P_2 - CG)
\]

Centroid = “CG”
One Example: Subdivision of a Sphere

It’s often useful to be able to parameterize a triangle into (s,t), like this:

\[ v(s,t) = V_0 + s(V_1-V_0) + t(V_2-V_0) \]

Note! There is no place in this triangle where \( s = t = 1 \).
Example: Sphere Subdivision

Vertex spheresubd.vert
Geometry spheresubd.geom
Fragment spheresubd.frag
Program SphereSubd uLevel <0 0 10> uRadius <.5 1.5> uColor { 1. .5 .15 1. }

Triangles [ 0. 0. 1.] [ 1. 0. 0.] [0. 1. 0.]
Triangles [ 1. 0. 0.] [ 0. 0. -1.] [0. 1. 0.]
Triangles [ 0. 0. -1.] [-1. 0. 0.] [0. 1. 0.]
Triangles [-1. 0. 0.] [ 0. 0. 1.] [0. 1. 0.]

Triangles [ 0. 0. 1.] [ 1. 0. 0.] [0. -1. 0.]
Triangles [ 1. 0. 0.] [ 0. 0. -1.] [0. -1. 0.]
Triangles [ 0. 0. -1.] [-1. 0. 0.] [0. -1. 0.]
Triangles [-1. 0. 0.] [ 0. 0. 1.] [0. -1. 0.]
Example: Sphere Subdivision

spheresubd.vert

```cpp
void main( )
{
    gl_Position = gl_Vertex;
}
```

spheresubd.frag

```cpp
uniform vec4 uColor;
in float gLightIntensity;
void main( )
{
    gl_FragColor = vec4( gLightIntensity*uColor.rgb, 1. );
}
```

Example: Sphere Subdivision

spheresubd.geom

```cpp
#version 330 compatibility
#extension GL_EXT_gpu_shader4: enable
#extension GL_EXT_geometry_shader4: enable
layout( triangles ) in;
layout( triangle_strip, max_vertices=200 ) out;
uniform int uLevel;
uniform float uRadius;
out float gLightIntensity;
const vec3 LIGHTPOS = vec3( 0., 10., 0. );
vec3 V0, V01, V02;
void ProduceVertex( float s, float t )
{
    vec3 v = V0 + s*V01 + t*V02;
    v = normalize(v);
    vec3 n = v;
    vec3 tnorm = normalize( gl_NormalMatrix * n );  // the transformed normal
    vec4 ECposition = gl_ModelViewMatrix * vec4( (uRadius*v), 1. );
    gLightIntensity = abs( dot( normalize(LIGHTPOS - ECposition.xyz), tnorm ) );
    gl_Position = gl_ProjectionMatrix * ECposition;
    EmitVertex( );
}
```
void main( )
{
  V01 = ( gl_PositionIn[1] - gl_PositionIn[0] ).xyz;
  V02 = ( gl_PositionIn[2] - gl_PositionIn[0] ).xyz;
  V0 =  gl_PositionIn[0].xyz;
  int numLayers = 1 << uLevel;
  float dt = 1. / float( numLayers );
  float t_top = 1. ;
  for( int it = 0; it < numLayers; it++ )
  {
    . . .
  }

for( int it = 0; it < numLayers; it++ )
{
  float t_bot = t_top - dt;
  float smax_top = 1. - t_top;
  float smax_bot = 1. - t_bot;
  int nums = it + 1;
  float ds_top = smax_top / float( nums - 1 );
  float ds_bot = smax_bot / float( nums );
  float s_top = 0.;
  float s_bot = 0.;
  for( int is = 0; is < nums; is++ )
  {
    ProduceVertex( s_bot, t_bot );
    ProduceVertex( s_top, t_top );
    s_top += ds_top;
    s_bot += ds_bot;
  }
  ProduceVertex( s_bot, t_bot );
  EndPrimitive( );
  t_top = t_bot;
  t_bot -= dt;
}

Example: Sphere Subdivision

spheresubd.geom
Example: Sphere Subdivision with One triangle

Level = 0

Level = 1

Level = 2

Level = 3

Example: Sphere Subdivision with the Whole Sphere (8 triangles)

Level = 0

Level = 1

Level = 2

Level = 3
Another Example: Explosion

1. Break the triangles into points
2. Treat each point's distance from the triangle's CG as an initial velocity
3. Follow the laws of projectile motion:

\[ x = x_0 + v_x t \]
\[ y = y_0 + v_y t + \frac{1}{2} a_y t^2 \]

Example: Explosion

```cpp
#version 330 compatibility
#extension GL_EXT_gpu_shader4: enable
#extension GL_EXT_geometry_shader4: enable
layout( triangles ) in;
layout( points, max_vertices=200 ) out;
uniform int uLevel;
uniform float uGravity;
uniform float uTime;
uniform float uVelScale;
vec3 V0, V01, V02;
vec3 CG;
void ProduceVertex( float s, float t )
{
  vec3 v = V0 + s*V01 + t*V02;
  vec3 vel = uVelScale * ( v - CG );
  v = CG + vel*uTime + 0.5*vec3(0.,uGravity,0.)*uTime*uTime;
  gl_Position = gl_ProjectionMatrix * vec4( v, 1. );
  EmitVertex();
}
```
Example: Explosion

```c
void main() {
    V01 = (gl_PositionIn[1] - gl_PositionIn[0]).xyz;
    V02 = (gl_PositionIn[2] - gl_PositionIn[0]).xyz;
    V0 = gl_PositionIn[0].xyz;
    CG = (gl_PositionIn[0].xyz + gl_PositionIn[1].xyz + gl_PositionIn[2].xyz) / 3.;
    int numLayers = 1 << uLevel;
    float dt = 1. / float(numLayers);
    float t = 1.;
    for(int it = 0; it <= numLayers; it++) {
        float smax = 1. - t;
        int nums = it + 1;
        float ds = smax / float(nums - 1);
        float s = 0.;
        for(int is = 0; is < nums; is++) {
            ProduceVertex(s, t);
            s += ds;
        }
        t -= dt;
    }
}
```
Another Example: Silhouettes

1. Compute the normals of each of the four triangles
2. If there is a sign difference between the z component of the center triangle's normal and the z component of an adjacent triangle's normal, draw their common edge

I.e., you are looking for a crease.

Example: Silhouettes

silh.glib

Obj bunny.obj
Vertex silh.vert
Geometry silh.geom
Fragment silh.frag
Program Silhouette uColor { 0. 1. 0. 1. }

ObjAdj bunny.obj
Example: Silhouettes

**silh.vert**

```c
void main()
{
    gl_Position = gl_ModelViewMatrix * gl_Vertex;
}
```

**silh.frag**

```c
uniform vec4 uColor;

void main()
{
    gl_FragColor = vec4( uColor.rgb, 1.);
}
```

**silh.geom**

```c
#include <GL/glext.h>

#version 330 compatibility

#extension GL_EXT_gpu_shader4: enable
#extension GL_EXT_geometry_shader4: enable

layout( triangles_adjacency ) in;
layout( line_strip, max_vertices=200 ) out;

void main()
{
    vec3 V0 = gl_PositionIn[0].xyz;
    vec3 V1 = gl_PositionIn[1].xyz;
    vec3 V2 = gl_PositionIn[2].xyz;
    vec3 V3 = gl_PositionIn[3].xyz;
    vec3 V4 = gl_PositionIn[4].xyz;
    vec3 V5 = gl_PositionIn[5].xyz;

    vec3 N042 = cross( V4-V0, V2-V0 ); // the center triangle's normal
    vec3 N021 = cross( V2-V0, V1-V0 );
    vec3 N243 = cross( V4-V2, V3-V2 );
    vec3 N405 = cross( V0-V4, V5-V4 );

    if( dot( N042, N021 ) < 0. )   // make sure each outer triangle's
        N021 = vec3(0.,0.,0.) - N021;   // normal is in the same general direction
    if( dot( N042, N243 ) < 0. )
        N243 = vec3(0.,0.,0.) - N243;
    if( dot( N042, N405 ) < 0. )
        N405 = vec3(0.,0.,0.) - N405;
```
if( N042.z * N021.z <= 0. )
{
    gl_Position = gl_ProjectionMatrix * vec4( V0, 1. );
    EmitVertex( );
    gl_Position = gl_ProjectionMatrix * vec4( V2, 1. );
    EmitVertex( );
    EndPrimitive( );
}

if( N042.z * N243.z <= 0. )
{
    gl_Position = gl_ProjectionMatrix * vec4( V2, 1. );
    EmitVertex( );
    gl_Position = gl_ProjectionMatrix * vec4( V4, 1. );
    EmitVertex( );
    EndPrimitive( );
}

if( N042.z * N405.z <= 0. )
{
    gl_Position = gl_ProjectionMatrix * vec4( V4, 1. );
    EmitVertex( );
    gl_Position = gl_ProjectionMatrix * vec4( V0, 1. );
    EmitVertex( );
    EndPrimitive( );
}
Another Example: Hedgehog Plots

```glsl
#version 330 compatibility
#extension GL_EXT_gpu_shader4: enable
#extension GL_EXT_geometry_shader4: enable
layout( triangles ) in;
layout( line_strip, max_vertices=200 ) out;
uniform int uDetail;
uniform float uDroop;
uniform int uLength;
uniform float uStep;
in vec3 vTnorm[3];
in vec4 vColor[3];
out vec4 gColor;
int ILength;
vec3 Norm[3];
vec3 N0, N01, N02;
vec4 V0, V01, V02;
void ProduceVertices( float s, float t )
{
  vec4 v = V0 + s*V01 + t*V02;
  vec3 n = normalize( N0 + s*N01 + t*N02 );
  for( int i = 0; i <= uLength; i++ )
  {
    gl_Position = gl_ProjectionMatrix * v;
    gColor = vColor[0];
    EmitVertex();
    v.xyz += uStep * n;
    v.y -= uDroop * float(i*i);
  }
  EndPrimitive();
}
```

hedgehog.geom, I
void main( )
{
    V0 = gl_PositionIn[0];
    V01 = ( gl_PositionIn[1] - gl_PositionIn[0] );
    V02 = ( gl_PositionIn[2] - gl_PositionIn[0] );
    Norm[0] = V0norm[0];
    Norm[1] = V0norm[1];
    Norm[2] = V0norm[2];
    if( dot( Norm[0], Norm[1] ) < 0. )
        Norm[1] = -Norm[1];
    if( dot( Norm[0], Norm[2] ) < 0. )
        Norm[2] = -Norm[2];
    N0   = normalize( Norm[0] );
    N01 = normalize( Norm[1] - Norm[0] );
    N02 = normalize( Norm[2] - Norm[0] );
    int numLayers = 1 << uDetail;
    float dt = 1. / float( numLayers );
    float t = 1.;
    for( int it = 0; it <= numLayers; it++ )
    {
        float smax = 1. - t;
        int nums = it + 1;
        float ds = smax / float( nums - 1 );
        float s = 0.;
        for( int is = 0; is < nums; is++ )
        {
            ProduceVertices( s, t );
            s += ds;
        }
        t -= dt;
    }
Ducky Hedgehog Plot

Hedgehog Plots Gone Wild
A GLSL Built-in Variable for the Geometry Shaders

int gl_PrimitiveIDIn

- Tells the number of primitives processed since the last time glBegin( ) was called
- Calling a vertex buffer drawing function counts as an implied glBegin( )
- gl_PrimitiveIDIn is 0 for the first primitive after the glBegin( )

Geometry shaders can set the built-in variable gl_PrimitiveID to send a primitive number to the fragment shader

What Happens if you Exceed the Maximum Allowed Emitted Vertices?

New in GLSL 4.x – you can loop back through the Geometry Shader multiple times
