OpenCL / OpenGL Vertex Interoperability: The Basic Idea

Your C++ program writes initial values into the buffer on the GPU

OpenCL acquires the buffer

Each OpenCL kernel reads an (x,y,z) value from the buffer

(x,y,z) Vertex Data in an OpenGL Buffer

Each OpenCL kernel updates its (x,y,z) value

Each OpenCL kernel writes its (x,y,z) value back to the buffer

OpenCL releases the buffer

OpenGL draws using the (x,y,z) values in the buffer on the GPU

Some of the Inner Workings of OpenGL: Feel Free to Detour Right to Slide #23

Your C++ program writes initial values into the buffer on the GPU

OpenGL draws using the (x,y,z) values in the buffer on the GPU

In the Beginning of OpenGL …

You listed the vertices with separate function calls:

```c
glBegin( GL_TRIANGLES );
glVertex3f( x0, y0, z0 );
glVertex3f( x1, y1, z1 );
glVertex3f( x2, y2, z2 );
glVertex3f( x0, y0, z0 );
glVertex3f( x3, y3, z3 );
glVertex3f( x4, y4, z4 );
glEnd();
```

Then someone noticed how inefficient that was, for three reasons:

1. Sending large amounts of small pieces of information is less efficient than sending small amounts of large pieces of information
2. The vertex coordinates were being listed in the CPU and were being transferred to the GPU every drawing pass
3. Some vertices were listed twice
Here's What OpenGL Has Been Moving To: Vertex Buffer Objects

```c
GLfloat CubeVertices[][3] = {
    { -1., -1., -1. },
    {  1., -1., -1. },
    { -1.,  1., -1. },
    {  1.,  1., -1. },
    { -1., -1.,  1. },
    {  1., -1.,  1. },
    { -1.,  1.,  1. },
    {  1.,  1.,  1. }
};

GLfloat CubeColors[][3] = {
    { 0., 0., 0. },
    { 1., 0., 0. },
    { 0., 1., 0. },
    { 1., 1., 0. },
    { 0., 0., 1. },
    { 1., 0., 1. },
    { 0., 1., 1. },
    { 1., 1., 1. }
};

GLuint CubeIndices[][4] = {
    { 0, 2, 3, 1 },
    { 4, 5, 7, 6 },
    { 1, 3, 7, 5 },
    { 0, 4, 6, 2 },
    { 2, 6, 7, 3 },
    { 0, 1, 5, 4 }
};
```

A Little Background -- the OpenGL Rendering Context

The OpenGL Rendering Context contains all the characteristic information necessary to produce an image from geometry. This includes transformations, colors, lighting, textures, where to send the display, etc.

If we were implementing the OpenGL state as a C++ structure, we might do something like this:

```c
struct context {
    float [4][4] Transformation;
    struct Texture * Texture0;
    struct DataArrayBuffer * ArrayBuffer;
    ...;
};
```

More Background – How do you create a special OpenGL Array Buffer called a Vertex Buffer Object?

In C++, objects are pointed to by their address. In OpenGL, objects are pointed to by an unsigned integer handle. You can assign a value for this handle yourself (not recommended), or have OpenGL generate one for you that is guaranteed to be unique. For example:

```c
GLuint buf;
glGenBuffers( 1, &buf );
```

This doesn’t actually allocate memory for the buffer object yet, it just acquires a unique handle. To allocate memory, you need to bind this handle to the Context.

More Background – What is an OpenGL “Object”?

An OpenGL Object is pretty much the same as a C++ object: it encapsulates a group of data items and allows you to treat them as a unified whole. For example, a Data Array Buffer Object could be defined in C++ by:

```c
struct DataArrayBuffer {
    enum dataType;
    void * memStart;
    int memSize;
};
```

Then, you could create any number of Buffer Object instances, each with its own characteristics encapsulated within it. When you want to make that combination current, you just need to point the ArrayBuffer element of the Context to that entire struct (“bind”). When you bind an object, all of its information comes with it.
A Little Background -- the OpenGL Rendering Context

It's very fast to re-bind a different vertex buffer. It amounts to just changing a pointer.

```c
glBindBuffer( GL_ARRAY_BUFFER, buf );
```

More Background -- “Binding” to the Context

The OpenGL term “binding” refers to “attaching” or “docking” (a metaphor which I find to be more visually pleasing) an OpenGL object to the Context. You can then assign characteristics, and they will “flow” through the Context into the object.

```c
glBindBuffer( GL_ARRAY_BUFFER, buf );
glBufferData( GL_ARRAY_BUFFER, numBytes, data, usage );
```

Think of it as happening this way:

```c
Context.ArrayBuffer.memStart = CopyToGpuMemory( data, numBytes );
Context.ArrayBuffer.memSize = numBytes;
```

More Background -- “Binding” to the Context

When you want to use that Vertex Buffer Object, just bind it again. All of the characteristics will then be active, just as if you had specified them again.

```c
glBindBuffer( GL_ARRAY_BUFFER, buf );
```

Think of it as happening this way:

```c
float *data = Context.ArrayBuffer.memStart;
```

Vertex Buffers: Putting Data in the Buffer Object

```c
glBufferData( type, numBytes, data, usage );
```

*type* is the type of buffer object this is: `GL_ARRAY_BUFFER` to store floating point vertices, normals, colors, and texture coordinates

*numBytes* is the number of bytes to store in all. Not the number of numbers, but the number of bytes!

*data* is the memory address of (i.e., pointer to) the data to be transferred to the graphics card. This can be NULL, and the data can be transferred later via memory-mapping.
Preview: We are going to use a Particle System as a Case Study

Vertex Buffers: Putting Data in the Buffer Object

```c
glBufferData( type, numbytes, data, usage );
```

Usage is a hint as to how the data will be used: GL_xxx_yyy

where xxx can be:
- STREAM: this buffer will be written lots
- STATIC: this buffer will be written seldom and read seldom
- DYNAMIC: this buffer will be written often and used often

and yyy can be:
- DRAW: this buffer will be used for drawing
- READ: this buffer will be copied into
- COPY: not a real need for now, but someday…

GL_STATIC_DRAW is the most common usage

Vertex Buffers: Step #1 – Fill the Arrays

```c
GLfloat Vertices[ ][3] =
{
  { 1., 2., 3. },
  { 4., 5., 6. },
  ...,
};
```

```c
int numVertices = sizeof(Vertices) / ( 3*sizeof(GLfloat) );
```

Vertex Buffers: Step #2 – Create the Buffers and Fill Them

```c
glGenBuffers( 1, &buf );
glBindBuffer( GL_ARRAY_BUFFER, buf );
glBufferData( GL_ARRAY_BUFFER, 3*sizeof(GLfloat)*numVertices, Vertices, GL_STATIC_DRAW );
```
Vertex Buffers: Step #3 – Activate the Array Types That You Will Use

```gl
glEnableClientState( type )
```

where type can be any of:

- `GL_VERTEX_ARRAY`
- `GL_COLOR_ARRAY`
- `GL_NORMAL_ARRAY`
- `GL_TEXTURE_COORD_ARRAY`

• Call this as many times as you need to enable all the arrays that you will need.
• There are other types, too.
• To deactivate a type, call:

```gl
glDisableClientState( type )
```

Vertex Buffers: Step #4 – To Draw, First Bind the Buffers

```gl
glBindBuffer( GL_ARRAY_BUFFER, buf );
```

Vertex Buffers: Step #5 – Specify the Data

```c
glVertexPointer( size, type, stride, rel_address);
glColorPointer( size, type, stride, rel_address);
glNormalPointer( type, stride, rel_address);
glTexCoordPointer( size, type, stride, rel_address);
```

- `size` is the spatial dimension, and can be: 2, 3, or 4
- `type` can be:
  - `GL_SHORT`
  - `GL_INT`
  - `GL_FLOAT`
  - `GL_DOUBLE`
- `stride` is the byte offset between consecutive entries in the array (0 means tightly packed)
- `rel_address`, the 4th argument, is the relative byte address from the start of the buffer where the first element of this part of the data lives.

The Data Types in a vertex buffer object can be stored either as “packed” or “interleaved”

```c
gl*Pointer( size, type, stride, offset);
```

- `rel_address`, the 4th argument, is the relative byte address from the start of the buffer where the first element of this part of the data lives.

Packed:

```c
glVertexPointer( 3, GL_FLOAT, 3*sizeof(GLfloat), 0 );
glColorPointer( 3, GL_FLOAT, 3*sizeof(GLfloat), 3*numVertices*sizeof(GLfloat) );
```

Interleaved:

```c
glVertexPointer( 3, GL_FLOAT, 6*sizeof(GLfloat), 0 );
glColorPointer( 3, GL_FLOAT, 6*sizeof(GLfloat), 3*sizeof(GLfloat) );
```
Vertex Buffers: Step #6 – Specify the Connections

GLfloat Vertices[ 3 ] =
{
    { x0, y0, z0 },
    { x1, y1, z1 },
    { x2, y2, z2 },
    { x3, y3, z3 },
    { x4, y4, z4 },
    { x5, y5, z5 }
};

int numVertices = sizeof(Vertices) / ( 3*sizeof(GLfloat) );

glDrawArrays( GL_TRIANGLES, 0, numVertices );

Vertex Buffers: Writing Data Directly into a Vertex Buffer

Map the buffer from GPU memory into the memory space of the application:

glBindBuffer( buf, GL_ARRAY_BUFFER );
glBufferData( GL_ARRAY_BUFFER, 3*sizeof(float)*numVertices, NULL, GL_STATIC_DRAW );

float * vertexArray = glMapBuffer( GL_ARRAY_BUFFER, usage );

usage is an indication how the data will be used:
GL_READ_ONLY the vertex data will be read from, but not written to
GL_WRITE_ONLY the vertex data will be written to, but not read from
GL_READ_WRITE the vertex data will be read from and written to

You can now use vertexArray[] like any other floating-point array.

When you are done, be sure to call:

glUnMapBuffer( GL_ARRAY_BUFFER );

We Now Pickup with the OpenCL Stuff

Either OpenGL or OpenCL can use the Vertex Buffer at a time, but not both:

All of this happens on the GPU

Your C++ program writes initial values into the buffer on the GPU

OpenCL acquires the buffer

Each OpenCL kernel reads an (x,y,z) value from the buffer

Each OpenCL kernel updates its (x,y,z) value

Each OpenCL kernel writes its (x,y,z) value back to the buffer

OpenGL releases the buffer

OpenGL draws using the (x,y,z) values in the buffer on the GPU
#include <stdio.h>
#define USE_MATH_DEFINES
#include <math.h>
#include <string.h>
#include <stdlib.h>
#include <ctype.h>
#include <omp.h>
#ifdef WIN32
#include <windows.h>
#endif
#ifdef WIN32
#include "glew.h"
#endif
#include <GL/gl.h>
#include <GL/glu.h>
#include "glut.h"
#include "glui.h"
#include "CL/cl.h"
#include "CL/cl_gl.h"

1. Program Header

// structs we will need later:
struct xyzw {
    float x, y, z, w;
};

struct rgba {
    float r, g, b, a;
};

OpenCL Global Variables

size_t GlobalWorkSize[3] = { NUM_PARTICLES, 1, 1 };
size_t LocalWorkSize[3] = { LOCAL_SIZE, 1, 1 };

GLuint hPobj; // host opengl object for Points
GLuint hCobj; // host opengl object for Colors
struct xyzw * hVel; // host C++ array for Velocities
dcl_mem dPobj; // device memory buffer for Points
dcl_mem dCobj; // device memory buffer for Colors
dcl_mem dVel; // device memory buffer for Velocities
cl_command_queue CmdQueue;
cl_device_id Device;
cl_kernel Kernel;
cl_platform_id Platform;
cl_program Program;

A Deceptively-Simple Main Program

int main(int argc, char *argv[]) {
    glutInit(&argc, argv);
    InitGraphics();
    InitLists();
    InitCL();
    Reset();
    InitGlui();
    glutMainLoop();
    return 0;
}
### GLEW – the GL Extension Wrangler

```c
#ifdef WIN32
GLenum err = glewInit();
if (err != GLEW_OK)
{
    fprintf(stderr, "glewInit Error\n");
}
#endif

GLEW – the GL Extension Wrangler

This must wait to be called until after a graphics window is open!

Why? Because that’s when a graphics context is created.
```

### Setting up OpenCL: Querying the Existence of an OpenCL Extension

```c
void InitCL()
{
    ...
    status = clGetDeviceIDs(Platform, CL_DEVICE_TYPE_GPU, 1, &Device, NULL);
    PrintCLError(status, "clGetDeviceIDs: ");
    // since this is an openGl interoperability program,
    // check if the openGl sharing extension is supported
    // (no point going on if it isn’t):
    if( IsCLExtensionSupported("cl_khr_gl_sharing") )
    {
        fprintf(stderr, "cl_khr_gl_sharing is supported\n");
    } else
    {
        fprintf(stderr, "cl_khr_gl_sharing is not supported – sorry\n");
        return;
    }
}
```

### Setting up OpenCL: The Interoperability Context

```c
void InitCL()
{
    ...
    // get the platform id:
    status = clGetPlatformIDs(1, &Platform, NULL);
    PrintCLError(status, "clGetPlatformIDs: ");
    // get the device id:
    status = clGetDeviceIDs(Platform, CL_DEVICE_TYPE_GPU, 1, &Device, NULL);
    PrintCLError(status, "clGetDeviceIDs: ");
    // 3. create a special openCl context based on the openGl context:
    cl_context_properties props[ ] = {
        CL_GL_CONTEXT_KHR, (cl_context_properties) wglGetCurrentContext( ),
        CL_WGL_HDC_KHR, (cl_context_properties) wglGetCurrentDC( ),
        CL_CONTEXT_PLATFORM, (cl_context_properties) Platform,
    };
    cl_context Context = clCreateContext( props, 1, &Device, NULL, NULL, &status );
    PrintCLError(status, "clCreateContext: ");
}
```
Setting up OpenCL:
The Interoperability Context is Different for each OS (oh, good...)

For Windows:

```c
cl_context_properties props[ ] = {
    CL_GL_CONTEXT_KHR, (cl_context_properties) wglGetCurrentContext(),
    CL_WGL_HDC_KHR, (cl_context_properties) wglGetCurrentDC(),
    CL_CONTEXT_PLATFORM, (cl_context_properties) Platform, 0
};
cl_context Context = clCreateContext( props, 1, &Device, NULL, NULL, &status );
```

For Linux:

```c
cl_context_properties props[ ] = {
    CL_GL_CONTEXT_KHR, (cl_context_properties) glXGetCurrentContext(),
    CL_GLX_DISPLAY_KHR, (cl_context_properties) glXGetCurrentDisplay(),
    CL_CONTEXT_PLATFORM, (cl_context_properties) Platform, 0
};
cl_context Context = clCreateContext( props, 1, &Device, NULL, NULL, &status );
```

For Apple:

```c
cl_context_properties props[ ] = {
    CL_CONTEXT_PROPERTY_USE_CGL_SHAREGROUP_APPLE, (cl_context_properties) kCGLShareGroup, 0
};
cl_context Context = clCreateContext( props, 0, 0, NULL, NULL, &status );
```

Setting up OpenCL

```c
void InitCL() {
    // create the velocity array and the opengl vertex array buffer and color array buffer:
    delete [] hVel;
    hVel = new struct xyzw [ NUM_PARTICLES ];
    glGenBuffers( 1, &hPobj );
    glBindBuffer( GL_ARRAY_BUFFER, hPobj );
    glBufferData( GL_ARRAY_BUFFER, 4 * NUM_PARTICLES * sizeof(float), NULL, GL_STATIC_DRAW );
    glGenBuffers( 1, &hCobj );
    glBindBuffer( GL_ARRAY_BUFFER, hCobj );
    glBufferData( GL_ARRAY_BUFFER, 4 * NUM_PARTICLES * sizeof(float), NULL, GL_STATIC_DRAW );
    glBindBuffer( GL_ARRAY_BUFFER, 0 );
    // fill those arrays and buffers:
    ResetParticles();
}
```

"hVel" stands for "host Velocities"
"hPobj" stands for "host Points object"
"hCobj" stands for "host Colors object"

Setting the Initial Particle Parameters, I

```c
unsigned int Seed;

void ResetParticles() {
    glBindBuffer( GL_ARRAY_BUFFER, hPobj );
    struct xyzw *points = (struct xyzw *) glMapBuffer( GL_ARRAY_BUFFER, GL_WRITE_ONLY );
    for( int i = 0; i < NUM_PARTICLES; ++i ) {
        points[ i ].x = Ranf( &Seed, XMIN, XMAX );
        points[ i ].y = Ranf( &Seed, YMIN, YMAX );
        points[ i ].z = Ranf( &Seed, ZMIN, ZMAX );
        points[ i ].w = 1.;
    }
    glUnmapBuffer( GL_ARRAY_BUFFER );
    glBindBuffer( GL_ARRAY_BUFFER, hCobj );
    struct rgba *colors = (struct rgba *) glMapBuffer( GL_ARRAY_BUFFER, GL_WRITE_ONLY );
    for( int i = 0; i < NUM_PARTICLES; ++i ) {
        colors[ i ].r  = Ranf( &Seed, 0., 1. );
        colors[ i ].g = Ranf( &Seed, 0., 1. );
        colors[ i ].b = Ranf( &Seed, 0., 1. );
        colors[ i ].a = 1.;
    }
    glUnmapBuffer( GL_ARRAY_BUFFER );
}
```

Setting the Initial Particle Parameters, II

```c
for( int i = 0; i < NUM_PARTICLES; ++i ) {
    hVel[ i ].x = Ranf( &Seed, VMIN, VMAX );
    hVel[ i ].y = Ranf( &Seed, 0., VMAX );
    hVel[ i ].z = Ranf( &Seed, VMIN, VMAX );
    hVel[ i ].w = 0.;
}
```
### Setting up the Device-Side Buffers

```c
void InitCL()
{
    ...
    // 5. create the opencl version of the velocity array:
    dVel = clCreateBuffer( Context, CL_MEM_READ_WRITE, 4*sizeof(float)*NUM_PARTICLES, NULL, &status );
    PrintCLError( status, "clCreateBuffer: " );
    // 6. write the data from the host buffers to the device buffers:
    status = clEnqueueWriteBuffer( CmdQueue, dVel, CL_FALSE, 0, 4*sizeof(float)*NUM_PARTICLES, hVel, 0, NULL, NULL );
    PrintCLError( status, "clEnqueueWriteBuffer: " );
    // 5. create the opencl version of the opengl buffers:
    dPobj = clCreateFromGLBuffer( Context, CL_MEM_READ_WRITE, hPobj, &status );
    PrintCLError( status, "clCreateFromGLBuffer (1)" );
    dCobj = clCreateFromGLBuffer( Context, CL_MEM_READ_WRITE, hCobj, &status );
    PrintCLError( status, "clCreateFromGLBuffer (2)" );

    Note: you don't need an OpenGL-accessible buffer for the velocities. Velocities aren't needed for drawing. Velocities are only needed to update point positions. The velocity buffer can just be done internally to OpenCL.
```

### This is how OpenCL and OpenGL Share the Same Memory Buffer

This is how OpenCL and OpenGL Share the Same Memory Buffer

```c
{...}
```

### Setup the Kernel Arguments...

```c
void InitCL()
{
    ...
    // 10. setup the arguments to the Kernel object:
    status = clSetKernelArg( Kernel, 0, sizeof(cl_mem), &dPobj );
    PrintCLError( status, "clSetKernelArg (1): " );
    status = clSetKernelArg( Kernel, 1, sizeof(cl_mem), &dVel );
    PrintCLError( status, "clSetKernelArg (2): " );
    status = clSetKernelArg( Kernel, 2, sizeof(cl_mem), &dCobj );
    PrintCLError( status, "clSetKernelArg (3): " );

    kernel void Particle( global point * dPobj, global vector * dVel, global color * dCobj )
    {
        ... ...
    }
```

### The OpenGL "Idle Function" Tells OpenCL to Do Its Computing

```c
void Animate()
{
    // acquire the vertex buffers from OpenGL:
    glutSetWindow( MainWindow );
    glFinish( );
    cl_int status = clEnqueueAcquireGLObjects( CmdQueue, 1, &dPobj, 0, NULL, NULL );
    PrintCLError( status, "clEnqueueAcquireGLObjects (1) : " );
    status = clEnqueueAcquireGLObjects( CmdQueue, 1, &dCobj, 0, NULL, NULL );
    PrintCLError( status, "clEnqueueAcquireGLObjects (2) : " );
    Wait();
    double time0 = omp_get_wtime();
    // 11. enqueue the Kernel object for execution:
    cl_event wait;
    status = clEnqueueNDRangeKernel( CmdQueue, Kernel, 1, NULL, GlobalWorkSize, LocalWorkSize, 0, NULL, &wait );
    PrintCLError( status, "clEnqueueNDRangeKernel: " );
    Wait();
    double time1 = omp_get_wtime();
    ElapsedTime = time1 - time0;
    clFinish( CmdQueue );
    clEnqueueReleaseGLObjects( CmdQueue, 1, &dCobj, 0, NULL, NULL );
    PrintCLError( status, "clEnqueueReleaseGLObject (1): " );
    clEnqueueReleaseGLObjects( CmdQueue, 1, &dPobj, 0, NULL, NULL );
    PrintCLError( status, "clEnqueueReleaseGLObjects (2) : " );
    glutSetWindow( MainWindow );
    glutPostRedisplay();
}
```
This is how OpenCL Manages Exclusive Access to the Memory Buffer

```c
status = clEnqueueAcquireGLObjects( CmdQueue, 1, &dPobj, 0, NULL, NULL );
status = clEnqueueAcquireGLObjects( CmdQueue, 1, &dCobj, 0, NULL, NULL );

. . .

status = clEnqueueReleaseGLObjects( CmdQueue, 1, &dCobj, 0, NULL, NULL );
status = clEnqueueReleaseGLObjects( CmdQueue, 1, &dPobj, 0, NULL, NULL );
```

Redrawing the Scene:
The Particles

```c
void Display( )
{
    . . .
    glPointSize( 2. );
    glDrawArrays( GL_POINTS, 0, NUM_PARTICLES );
    glPointSize( 1. );
    glDisableClientState( GL_VERTEX_ARRAY );
    glDisableClientState( GL_COLOR_ARRAY );
    glBindBuffer( GL_ARRAY_BUFFER, 0 );
    glutSwapBuffers( );
    glFlush( );
}
```

Redraw the Scene:
The Performance

```c
void Display( )
{
    . . .
    if( ShowPerformance )
    {
        char str[128];
        sprintf( str, "%6.1f GigaParticles/Sec", (float)NUM_PARTICLES/ElapsedTime/1000000000. );
        glDisable( GL_DEPTH_TEST );
        glMatrixMode( GL_PROJECTION );
        glLoadIdentity( );
        gluOrtho2D( 0., 100., 0., 100. );
        glMatrixMode( GL_MODELVIEW );
        glLoadIdentity( );
        glColor3f( 1., 1., 1. );
        DoRasterString( 5., 5., 0., str );
    }
}
```

13. Clean-up

```c
void Quit( )
{
    Glui->close( );
    glutSetWindow( MainWindow );
    glFinish( );
    glutDestroyWindow( MainWindow );

    // 13. clean everything up:
    clReleaseKernel( Kernel );
    clReleaseProgram( Program );
    clReleaseCommandQueue( CmdQueue );
    clReleaseMemObject( dPobj );
    clReleaseMemObject( dCobj );
    exit( 0 );
}
```
```
typedef float4 point;
typedef float4 vector;
typedef float4 color;
typedef float4 sphere;

constant float4 G = (float4) ( 0., -9.8, 0., 0. );
constant float DT = 0.1;
constant sphere Sphere1 = (sphere)( -100., -800., 0., 600. );

bool IsInsideSphere( point p, sphere s ) {
    float r = fast_length( p.xyz - s.xyz );
    return ( r < s.w );
}

particles.cl

kernel void Particle( 
    global point * dPobj, 
    global vector * dVel, 
    global color * dCobj )
{
    int gid = get_global_id( 0 ); // particle #
    point p = dPobj[ gid ];
    vector v = dVel[ gid ];
    point pp = p + v*DT + G * (point)(.5*DT*DT); // p'
    vector vp = v + G*DT; // v'
    pp.w = 1.;
    vp.w = 0.;

    if( IsInsideSphere( pp, Sphere1 ) ) {
        vp = BounceSphere( p, v, Sphere1 );
        pp = p + vp*DT + G * (point)( .5*DT*DT );
    }
    dPobj[ gid ] = pp;
    dVel[ gid ] = vp;
}
```

```
vector Bounce( vector in, vector n ) {
    n.w = 0;
    n = normalize( n );
    vector out = in - n * (vector)( 2.*dot( in.xyz, n.xyz ) );
    out.w = 0;
    return out;
}

vector BounceSphere( point p, vector v, sphere s ) {
    vector n;
    n.xyz = fast_normalize( p.xyz - s.xyz );
    n.w = 0;
    return Bounce( in, n );
}

particles.cl
