Simple OpenMP

OpenMP Multithreaded Programming

• OpenMP stands for “Open Multi-Processing”
• It is run by a consortium of companies, labs, and universities
• OpenMP (IMHO) gives you the biggest multithread benefit per amount of work you have to put into using it

Much of your use of OpenMP will be accomplished by issuing C/C++ “pragmas” to tell the compiler how to build the threads into the executable

#pragma omp directive [clause]

That’s it! That’s where the compiler comes in.

But, as you are about to find out, doing parallel processing at all is not difficult.

The trick is doing parallel processing well. That’s where you come in.

Using OpenMP in Linux:

g++ -o proj proj.cpp -lm -fopenmp

Using OpenMP in Microsoft Visual Studio:

1. Go to the Project menu → Project Properties

2. Change the setting Configuration Properties → C/C++ → Language → OpenMP Support to “Yes (/openmp)”
Threads

We will get into more detail pretty soon, but for now, know that a thread is an independent execution path for your code to take.

Threads are at their very best when each one can run on a separate hardware core.

---

Seeing if OpenMP is Supported on Your System:

```c
#include <omp.h>

omp_set_num_threads( NUMT );

#pragma omp parallel for default(none)
for( int i = 0; i < arraySize; i++ )
{
    ...
    ...
}
```

This creates a team of threads from the thread pool and divides the for-loop passes up among those threads.

There is an "implied barrier" at the end where each thread waits until all threads are done, then the code continues in a single thread.

The `default(none)` directive forces you to explicitly declare all variables declared outside the parallel region to be either private or shared while they are in the parallel region. Variables declared within the for-loop statement are automatically private.
