Here’s What We Know So Far

- Vertex Shader
- Primitive Assembly
- Tessellation Control Shader
- Tessellation Primitive Generator
- Tessellation Evaluation Shader
- Primitive Assembly
- Geometry Shader
- Primitive Assembly
- Rasterizer
- Fragment Shader

= Fixed Function

= Programmable
Here’s What We Know So Far

One Vertex In

Vertex Shader

One Vertex Out
Here’s What We Want Next

Arrays of Vertices Out, Possibly with a Change of Topology
The Geometry Shader: Where Does it Fit in the Pipeline?

- **Fixed Function**
- **Programmable**

If a Geometry Shader is used, it is always the last stop before the Rasterizer.
Your application generates these
{ Points, Lines, Line Strip, Line Loop, Lines with Adjacency, Line Strip with Adjacency, Triangles, Triangle Strip, Triangle Fan, Triangles with Adjacency, Triangle Strip with Adjacency }

The driver translates them into one of these and feeds them one-at-a-time into the Geometry Shader
{ Point, Line, Line with Adjacency, Triangle, Triangle with Adjacency }

The Geometry Shader generates (almost) as many of these as it wants
{ Points, LineStrips, TriangleStrips }

There needn’t be any correlation between Geometry Shader input type and Geometry Shader output type. Points can generate triangles, triangles can generate triangle strips, points can generate points, etc.
Additional Topologies that Geometry Shaders made Available:

GL_LINES_ADJACENCY

GL_LINE_STRIP_ADJACENCY

GL_TRIANGLES_ADJACENCY

GL_TRIANGLE_STRIP_ADJACENCY
Adjacency Primitives (and what they do when not using shaders)

This is what Fixed-Function OpenGL expects these topologies to mean. In Shader World, they can mean whatever you want them to mean. In Shader World, it's just a way to get some number of vertices into a Geometry Shader.

**Lines with Adjacency**

4N vertices are given.
(where N is the number of line segments to draw).
A line segment is drawn between #1 and #2.
Vertices #0 and #3 are there to provide adjacency information.

**Line Strip with Adjacency**

N+3 vertices are given
(where N is the number of line segments to draw).
A line segment is drawn between #1 and #2, #2 and #3, …, #N and #N+1.
Vertices #0 and #N+2 are there to provide adjacency information.
Adjacency Primitives (and what they do when not using shaders)

**Triangles with Adjacency**

6N vertices are given (where N is the number of triangles to draw). Points 0, 2, and 4 define the triangle. Points 1, 3, and 5 tell where adjacent triangles are.

**Triangle Strip with Adjacency**

4+2N vertices are given (where N is the number of triangles to draw). Points 0, 2, 4, 6, 8, 10, … define the triangles. Points 1, 3, 5, 7, 9, 11, … tell where adjacent triangles are.
Adjacency Primitives (and what they do when you are using shaders)

In these examples, we will use the “with adjacency” primitives only as a way of importing some number of vertices into the geometry shader.

These are the most useful:

- GL_LINES_ADJACENCY 4 vertices
- GL_TRIANGLES_ADJACENCY 6 vertices
**What Do the Inputs to a Geometry Shader Look Like?**

If a Vertex Shader Writes Variables as:
- `gl_Position`
- `gl_PointSize`

In the Geometry Shader, the dimensions indicated by the variable `gl_VerticesIn`, although you will already know this by the type of geometry you are inputting:

<table>
<thead>
<tr>
<th>GL_Primitive Type</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>GL_POINTS</td>
<td>1</td>
</tr>
<tr>
<td>GL_LINES</td>
<td>2</td>
</tr>
<tr>
<td>GL_LINES_ADJACENCY</td>
<td>4</td>
</tr>
<tr>
<td>GL_TRIANGLES</td>
<td>3</td>
</tr>
<tr>
<td>GL_TRIANGLES_ADJACENCY</td>
<td>6</td>
</tr>
</tbody>
</table>

and will Write Them to the Fragment Shader as:

- `gl_Position`
- `gl_PointSize`
What Do the Outputs from a Geometry Shader Look Like?

Basically, they look like what you already know:

- `gl_Position`
- `gl_PointSize`
- Plus, any of your own variables that you have declared as `out`

When the Geometry Shader calls `EmitVertex()`

this set of variables is copied to an entry in the shader's Primitive Assembly step

When the Geometry Shader calls `EndPrimitive()`

the vertices that have been saved in the Primitive Assembly elements are then assembled, rasterized, etc.

Note: there is no “BeginPrimitive( )” function. It is implied by (1) the start of the Geometry Shader, or (2) returning from the EndPrimitive( ) call. Also, there is no need to call EndPrimitive( ) at the end of the Geometry Shader – it’s implied.
If you are using a Geometry Shader, then the GS must be used if you want to pass information from the Vertex Shader to the Fragment Shader.

That is, this is a pipeline. You cannot pass variables directly from the vertex shader to the fragment shader anymore.
Example: A Bézier Curve

\[ P(t) = (1 - t)^3 P_0 + 3t(1 - t)^2 P_1 + 3t^2 (1 - t) P_2 + t^3 P_3 \]

Need to pass 4 points in to define the curve. You need to pass N points out to draw the curve as a Line Strip.
Example: Expanding 4 Points into a Bezier Curve with a Variable Number of Line Segments

```glsl
Vertex beziercurve.vert
Geometry beziercurve.geom
Fragment beziercurve.frag
Program BezierCurve uNum <2 4 50>

LineWidth 3.
LinesAdjacency [0. 0. 0.] [1. 1. 1.] [2. 1. 2.] [3. -1. 0.]
```

```glsl
void main( )
{
    gl_Position = gl_ModelViewProjectionMatrix * gl_Vertex;
}
```

```glsl
void main( )
{
    gl_FragColor = vec4( 0., 1., 0., 1.);
}
```
Example: Expanding 4 Points into a Bezier Curve with a Variable Number of Line Segments

```cpp
#version 330 compatibility
#extension GL_EXT_gpu_shader4: enable
#extension GL_EXT_geometry_shader4: enable
layout( lines_adjacency ) in;
layout( line_strip, max_vertices=200 ) out;
uniform int uNum;
void main( )
{
    float dt = 1. / float(uNum);
    float t = 0.;
    for( int i = 0; i <= uNum; i++ )
    {
        float omt = 1. - t;
        float omt2 = omt * omt;
        float omt3 = omt * omt2;
        float t2 = t * t;
        float t3 = t * t2;
        vec4 xyzw = omt3 * gl_PositionIn[0].xyzw +
                    3. * t * omt2 * gl_PositionIn[1].xyzw +
                    3. * t2 * omt * gl_PositionIn[2].xyzw +
                    t3 * gl_PositionIn[3].xyzw;

        gl_Position = xyzw;
        EmitVertex( )
        t += dt;
    }
}
```

Note: layout directives are a GLSL-ism and are used to define what the storage looks like.
Example: Expanding 4 Points into a Bezier Curve with a Variable Number of Line Segments

uNum = 5

uNum = 25
Note: It would have made no Difference if the Matrix Transform had been done in the Geometry Shader Instead

beziercurve.vert

```glsl
void main( )
{
    gl_Position = gl_Vertex;
}
```

beziercurve.geom

```glsl
vec4 xyzw = omt3 * gl_PositionIn[0].xyzw +
3. * t * omt2 * gl_PositionIn[1].xyzw +
3. * t2 * omt * gl_PositionIn[2].xyzw +
t3 * gl_PositionIn[3].xyzw;

gl_Position = gl_ModelViewProjectionMatrix * xyzw;
EmitVertex( )
t += dt;
}
```
Another Example: Shrinking Triangles
Example: Shrinking Triangles

Centroid = “CG”

\[ CG = \left( P_0 + P_1 + P_2 \right) / 3. \]

\[ P_0' = CG + uShrink \cdot ( P_0 - CG ) \]
\[ P_1' = CG + uShrink \cdot ( P_1 - CG ) \]
\[ P_2' = CG + uShrink \cdot ( P_2 - CG ) \]
#version 400 compatibility

out vec3 vNormal;

void main( )
{
    vNormal = normalize( gl_NormalMatrix * gl_Normal );
    gl_Position = gl_Vertex;
}
#version 330 compatibility
#extension GL_EXT_gpu_shader4: enable
#extension GL_EXT_geometry_shader4: enable

layout( triangles ) in;
layout( triangle_strip, max_vertices=200 ) out;

uniform float uShrink;
in vec3 vNormal[3];
out float gLightIntensity;
const vec3 LIGHTPOS = vec3( 0., 10., 0. );
vec3 V[3];
vec3 CG;

void ProduceVertex( int v )
{
  gLightIntensity = dot( normalize(LIGHTPOS - V[v]), vNormal[v] );
  gLightIntensity = abs( gLightIntensity );
  gl_Position = gl_ModelViewProjectionMatrix * vec4( CG + uShrink * ( V[v] - CG ), 1. );
  EmitVertex( );
}

void main( )
{
  V[0] = gl_PositionIn[0].xyz;
  V[1] = gl_PositionIn[1].xyz;
  ProduceVertex( 0 );
  ProduceVertex( 1 );
  ProduceVertex( 2 );
}

Since you are multiplying by the ModelViewProjection matrix here, don’t multiply by any of these matrices in the vertex shader!
Another Example: Sphere Subdivision

It's often useful to be able to parameterize a triangle into (s,t), like this:

Note! There is no place inside this triangle where s = t = 1.

\[ v(s,t) = V0 + s \times (V1-V0) + t \times (V2-V0) \]
Example: Sphere Subdivision

- At uLevel = 0, numLayers = $2^{\text{level}} = 1$
- At uLevel = 1, numLayers = 2
- At uLevel = 2, numLayers = 4
### Example: Sphere Subdivision

```
spheresubd.glib

Vertex spheresubd.vert
Geometry spheresubd.geom
Fragment spheresubd.frag
Program SphereSubd uLevel <0 0 10> uRadius <.5 1.5> uColor { 1. .5 .15 1. }

Triangles [ 0. 0.  1.]  [ 1. 0.  0.]  [0.  1. 0.]
Triangles [ 1. 0.  0.]  [ 0. 0. -1.]  [0.  1. 0.]
Triangles [ 0. 0. -1.]  [-1. 0.  0.]  [0.  1. 0.]
Triangles [-1. 0.  0.]  [ 0. 0.  1.]  [0.  1. 0.]

Triangles [ 0. 0.  1.]  [ 1. 0.  0.]  [0. -1. 0.]
Triangles [ 1. 0.  0.]  [ 0. 0. -1.]  [0. -1. 0.]
Triangles [ 0. 0. -1.]  [-1. 0.  0.]  [0. -1. 0.]
Triangles [-1. 0.  0.]  [ 0. 0.  1.]  [0. -1. 0.]
```
Example: Sphere Subdivision

spheresubd.vert

```cpp
void
main( )
{
    gl_Position = gl_Vertex;
}
```

spheresubd.frag

```cpp
uniform vec4 uColor;
in float gLightIntensity;

void
main( )
{
    gl_FragColor = vec4( gLightIntensity*uColor.rgb, 1. );
}
```
Example: Sphere Subdivision

```cpp
spheresubd.geom

#version 330 compatibility
#extension GL_EXT_gpu_shader4: enable
#extension GL_EXT_geometry_shader4: enable
layout( triangles ) in;
layout( triangle_strip, max_vertices=200 ) out;

uniform int uLevel;
uniform float uRadius;
out float gLightIntensity;
const vec3 LIGHTPOS = vec3( 0., 10., 0. );

vec3 V0, V01, V02;

void ProduceVertex( float s, float t )
{
    vec3 v = V0 + s*V01 + t*V02;
    v = normalize(v);
    vec3 n = v;
    vec3 tnorm = normalize( gl_NormalMatrix * n );  // the transformed normal

    vec4 ECposition = gl_ModelViewMatrix * vec4( (uRadius*v), 1. );
    gLightIntensity = abs( dot( normalize(LIGHTPOS - ECposition.xyz), tnorm ) );
    gl_Position = gl_ProjectionMatrix * ECposition;
    EmitVertex( );
}
```

Since you are multiplying by the ModelView and Projection matrices here, don’t multiply by any of these matrices in the vertex shader!
Example: Sphere Subdivision

spheresubd.geom

```c
void main( )
{
    V01 = ( gl_PositionIn[1] - gl_PositionIn[0] ).xyz;
    V02 = ( gl_PositionIn[2] - gl_PositionIn[0] ).xyz;
    V0  =   gl_PositionIn[0].xyz;

    int numLayers = 1 << uLevel;

    float dt = 1. / float( numLayers );

    float t_top = 1.;

    for( int it = 0; it < numLayers; it++ )
    {
        ...
    }
}
```
for( int it = 0; it < numLayers; it++ )
{
    float t_bot = t_top - dt;
    float smax_top = 1. - t_top;
    float smax_bot = 1. - t_bot;

    int nums = it + 1;
    float ds_top = smax_top / float(nums - 1);
    float ds_bot = smax_bot / float(nums);

    float s_top = 0.;
    float s_bot = 0.;

    for( int is = 0; is < nums; is++ )
    {
        ProduceVertex( s_bot, t_bot );
        ProduceVertex( s_top, t_top );
        s_top += ds_top;
        s_bot += ds_bot;
    }

    ProduceVertex( s_bot, t_bot );
    EndPrimitive( );

    t_top = t_bot;
    t_bot -= dt;
}
Example: Sphere Subdivision with One triangle

Level = 0

Level = 1

Level = 2

Level = 3
Example: Sphere Subdivision with the Whole Sphere (8 triangles)

Level = 0

Level = 1

Level = 2

Level = 3
Another Example: Explosion

1. Break the triangles into points
2. Treat each point’s distance from the triangle’s CG as an initial velocity
3. Follow the laws of projectile motion:

\[
x = x_0 + v_x t
\]

\[
y = y_0 + v_y t + \frac{1}{2} a_y t^2
\]
Example: Explosion

```cpp
void main( )
{
    gl_Position = gl_ModelViewMatrix * gl_Vertex;
}
```

Since you are multiplying by the Projection matrix in the geometry shader, don’t also multiply by it in the vertex shader!
Example: Explosion

```c
void main( )
{
    V01 = ( gl_PositionIn[1] - gl_PositionIn[0] ).xyz;
    V02 = ( gl_PositionIn[2] - gl_PositionIn[0] ).xyz;
    V0 =   gl_PositionIn[0].xyz;
    CG = ( gl_PositionIn[0].xyz + gl_PositionIn[1].xyz + gl_PositionIn[2].xyz ) / 3.;

    int numLayers = 1 << uLevel;

    float dt = 1. / float( numLayers );
    float t = 1.;

    for( int it = 0; it <= numLayers; it++ )
    {
        float smax = 1. - t;
        int nums = it + 1;
        float ds = smax / float( nums - 1 );
        float s = 0.;

        for( int is = 0; is < nums; is++ )
        {
            ProduceVertex( s, t );
            s += ds;
        }
        t -= dt;
    }
}
```
Example: Explosion
Another Example: Silhouettes

1. Compute the normal vectors of each of the four triangles (one in the center and three around the outside)

2. If there is a sign difference between the z component of the center triangle’s normal and the z component of an adjacent triangle’s normal, draw their common edge

I.e., you are looking for a crease.
Example: Silhouettes

```
silh.glib

Obj bunny.obj
Vertex   silh.vert
Geometry silh.geom
Fragment  silh.frag
Program   Silhouette  uColor { 0. 1. 0. 1. }
ObjAdj    bunny.obj
```
Example: Silhouettes

silh.vert

```c
void
main( )
{
    gl_Position = gl_ModelViewMatrix * gl_Vertex;
}
```

silh.frag

```c
uniform vec4 uColor;
void
main( )
{
    gl_FragColor = vec4( uColor.rgb, 1. );
}
```
#version 330 compatibility
#extension GL_EXT_gpu_shader4: enable
#extension GL_EXT_geometry_shader4: enable
layout( triangles_adjacency ) in;
layout( line_strip, max_vertices=200 ) out;
void main( )
{
    vec3 V0 = gl_PositionIn[0].xyz;
    vec3 V1 = gl_PositionIn[1].xyz;
    vec3 V2 = gl_PositionIn[2].xyz;
    vec3 V3 = gl_PositionIn[3].xyz;
    vec3 V4 = gl_PositionIn[4].xyz;
    vec3 V5 = gl_PositionIn[5].xyz;

    vec3 N042 = cross( V4-V0, V2-V0 ); // the center triangle’s normal
    vec3 N021 = cross( V2-V0, V1-V0 );
    vec3 N243 = cross( V4-V2, V3-V2 );
    vec3 N405 = cross( V0-V4, V5-V4 );

    if( dot( N042, N021 ) < 0. ) // make sure each outer triangle's
        N021 = vec3(0.,0.,0.) - N021; // normal is in the same general direction
    if( dot( N042, N243 ) < 0. )
        N243 = vec3(0.,0.,0.) - N243;
    if( dot( N042, N405 ) < 0. )
        N405 = vec3(0.,0.,0.) - N405;
}
if( N042.z * N021.z <= 0. )
{
    gl_Position = gl_ProjectionMatrix * vec4( V0, 1. );
    EmitVertex( );
    gl_Position = gl_ProjectionMatrix * vec4( V2, 1. );
    EmitVertex( );
    EndPrimitive( );
}

if( N042.z * N243.z <= 0. )
{
    gl_Position = gl_ProjectionMatrix * vec4( V2, 1. );
    EmitVertex( );
    gl_Position = gl_ProjectionMatrix * vec4( V4, 1. );
    EmitVertex( );
    EndPrimitive( );
}

if( N042.z * N405.z <= 0. )
{
    gl_Position = gl_ProjectionMatrix * vec4( V4, 1. );
    EmitVertex( );
    gl_Position = gl_ProjectionMatrix * vec4( V0, 1. );
    EmitVertex( );
    EndPrimitive( );
}

}

Ducky Hedgehog Plot
Hedgehog Plots Gone Wild
A GLSL Built-in Variable for the Geometry Shaders

int gl_PrimitiveIDIn

- Tells the number of primitives processed since the last time glBegin() was called
- Calling a vertex buffer drawing function counts as an implied glBegin()
- gl_PrimitiveIDIn is 0 for the first primitive after the glBegin()

Geometry shaders can set the built-in variable gl_PrimitiveID to send a primitive number to the fragment shader
What Happens if you Exceed the Maximum Allowed Emitted Vertices?

New in GLSL 4.x – you can loop back through the Geometry Shader multiple times
