Using Fragment Shaders to Manipulate Images

The Basic Idea: Wrap an Image Around a Piece of Geometry

In software, this is a very slow process. In hardware, this is very fast. The development of texture-mapping hardware was one of the most significant events in the history of computer graphics. This is really what finally enabled game development on a realistic scale.

The Basic Ideas

To prevent confusion, the texture image pixels are not called *pixels*. A pixel is an RGB dot in the final screen image. An RGB dot in the texture image is called a *texture element*, or *texel*.

Similarly, to avoid terminology confusion, a texture image's width and height dimensions are not called *X* and *Y*. They are called *S* and *T*.

A texture image is not indexed by its actual resolution coordinates. Instead, it is indexed by a coordinate system that is resolution-independent. The left side is always *S*=0, the right side is *S*=1, the bottom is *T*=0, and the top is *T*=1.

Thus, you do not need to be aware of the texture’s resolution when you are specifying coordinates that point into it. Think of *S* and *T* as a measure of what fraction of the way you are into the texture.

The Basic Ideas

Texture mapping is a computer graphics operation in which a separate image, referred to as the *texture*, is stretched onto a piece of 3D geometry and follows it however it is transformed. This image is also known as a *texture map*. This can be any image. *It can also be data. Afterall, the contents of a texture are just numbers.*
The Basic Ideas

The mapping between the geometry of the 3D object and the S and T of the texture image works like this:

\[ T = 0, \quad S = 0 \]
\[ T = 1, \quad S = 0 \]
\[ T = 0, \quad S = 1 \]
\[ T = 1, \quad S = 1 \]

You specify an (s,t) pair at each vertex, along with the vertex coordinate. At the same time that OpenGL is interpolating the coordinates, colors, etc. inside the polygon, it is also interpolating the (s,t) coordinates. Then, when OpenGL goes to draw each pixel, it uses that pixel’s interpolated (s,t) to lookup a color in the texture image.

Using a Texture: Assigning an (s,t) to each vertex

Enable texture mapping:
```
glEnable( GL_TEXTURE_2D );
```

Draw your polygons, specifying s and t at each vertex:
```
glBegin( GL_TRIANGLES );
    glTexCoord2f( s0, t0 );
    glNormal3f( nx0, ny0, nz0 );
    glVertex3f( x0, y0, z0 );
    glTexCoord2f( s1, t1 );
    glNormal3f( nx1, ny1, nz1 );
    glVertex3f( x1, y1, z1 );
    ... 
    glEnd( );
```

(If this geometry is static, i.e., will never change, it is a good idea to put this all into a display list.)

Disable texture mapping:
```
glDisable( GL_TEXTURE_2D );
```

Texture Image Basics in Shaders

Index the image using the usual texture indexing

\[ (0 \leq s, t \leq 1) \]

When you get back an RGB from the texture, remember that, if the texture’s numbers are colors:

\[ (0 \leq r, g, b \leq 1) \]

If the texture contains data, then the numbers can be anything.

Also, if you need to know the texel resolution of this texture, do this:
```
ivec2 ires = textureSize( uImageUnit, 0 );
float ResS = float( ires.s );
float ResT = float( ires.t );
```

Thus, to get from the current texel’s (s,t) to a neighboring texel’s (s,t), add
\[ \pm (1/ResS, 1/ResT) \]

A Good Example of Manipulating RGB Numbers – the Image Negative

Image RGB values are just numbers – they can be manipulated any way you’d like!

\[ (R, G, B) \rightarrow (1.-R, 1.-G, 1.-B) \]

**Toon Rendering**

Hand-drawn cartoons have a unique style, typically characterized by:

1. Dark outlines between the important elements in the scene
2. A reduced collection of available colors (i.e., no smooth shading)
