Why Two URLs?

http://mpi-forum.org
This is the definitive reference for the MPI standard. Go here if you want to read the official specification, which, BTW, continues to evolve.

https://www.open-mpi.org/
This consortium formed later. This is the open source version of MPI. If you want to start using MPI, I recommend you look here. This is the MPI that the COE systems use

https://www.open-mpi.org/doc/v4.0/
This URL is also really good – it is a link to all of the MPI man pages
Programs on different CPUs coordinate computations by passing messages between each other.

Note: Each CPU in the MPI "cluster" must be prepared ahead of time by having the MPI server code installed on it. Each MPI CPU must also have an integer ID assigned to it (called its rank).
How to SSH to the COE MPI Cluster

```
flip3 151% ssh submit-c@hpc.engr.oregonstate.edu
```

Type these two lines right away to set your paths correctly

**BTW, you can find out more about the COE cluster here:**
https://it.engineering.oregonstate.edu/hpc

“The College of Engineering HPC cluster is a heterogeneous mix of 202 servers providing over 3600 CPU cores, over 130 GPUs, and over 31 TB total RAM. The systems are connected via gigabit ethernet, and most of the latest servers also utilize a Mellanox EDR InfiniBand network connection. The cluster also has access to 100TB global scratch from the College of Engineering’s Dell/EMC Isilon enterprise storage.”
Compiling and Running

\[
\text{mpicc} \ -o \ \text{program} \ \text{program.c...} \\
\text{or} \\
\text{mpic++} \ -o \ \text{program} \ \text{program.cpp...}
\]

\text{C} \quad \text{C++}

\text{mpiexec} -mca btl self,tcp -np 4 \text{ program}

All distributed processors execute the same program at the same time

# of processors to use

Warning – use \text{mpic++} and \text{mpiexec}!

Don’t use g++ and don’t run by just typing the name of the executable!

Running with a \textit{bash} Batch Script

\texttt{submit.bash:}

\texttt{#!/bin/bash}
\texttt{#SBATCH -J AutoCorr}
\texttt{#SBATCH -A cs475-575}
\texttt{#SBATCH -p class}
\texttt{#SBATCH -N 4 \ # number of nodes}
\texttt{#SBATCH -n 4 \ # number of tasks}
\texttt{#SBATCH --constraint=ib}
\texttt{#SBATCH -o autocorr.out}
\texttt{#SBATCH -e autocorr.err}
\texttt{#SBATCH --mail-type=END,FAIL}
\texttt{#SBATCH --mail-user=joeparallel@cs.oregonstate.edu}
\texttt{module load openmpi}
\texttt{mpic++ autocorr.cpp -o autocorr -lm}
\texttt{mpiexec -mca btl self,tcp -np 4 ./autocorr}

\textbf{submit-c 143\% sbatch submit.bash}

Submitted batch job 258759
Auto-Notifications via Email

#SBATCH --mail-user=joeparallel@oregonstate.edu

You don’t have to ask for email notification, but if you do, please, please, please be sure you get your email address right!

The IT people are getting real tired of fielding the bounced emails when people spell their own email address wrong.

Use slurm’s `scancel` if your Job Needs to Be Killed

```
submit-c 143% sbatch submit.bash
Submitted batch job 258759

submit-c 144% scancel 258759
```
Setting Up and Finishing

```c
#include <mpi.h>

int main( int argc, char *argv[] )
{
  ...
  MPI_Init( &argc, &argv );
  ...
  MPI_Finalize( );
  return 0;
}
```

You don’t need to process command line arguments if you don’t need to.
You can also call it as:

```
MPI_Init( NULL, NULL );
```

MPI Follows a Single-Program-Multiple-Data (SPMD) Model

A **communicator** is a collection of CPUs that are capable of sending messages to each other.

Getting information about our place in the **communicator**:

```c
int numCPUs; // total # of cpus involved
int me; // which one I am
MPI_Comm_size( MPI_COMM_WORLD, &numCPUs );
MPI_Comm_rank( MPI_COMM_WORLD, &me );
```

Size, i.e., how many altogether?

Rank, i.e., which one am I?

It is then each CPU's job to figure out what piece of the overall problem it is responsible for and then go do it.

This requires MPI server code getting installed on all those CPUs. Only an administrator can do this.

```c
#include <stdio.h>
#include <math.h>
#include <mpi.h>

#define BOSS 0

int main( int argc, char *argv[] )
{
    MPI_Init( &argc, &argv );
    int numCPUs;       // total # of cpus involved
    int me;            // which one I am
    MPI_Comm_size( MPI_COMM_WORLD, &numCPUs );
    MPI_Comm_rank( MPI_COMM_WORLD, &me );

    if( me == BOSS )
        fprintf( stderr, "Rank %d says that we have a Communicator of size %d\n", BOSS, numCPUs );
    else
        fprintf( stderr, "Welcome from Rank %d\n", me );

    MPI_Finalize( );
    return 0;
}
```

A First Test of MPI

```

So, we have a group (a “communicator”) of distributed processors. How do they communicate about what work they are supposed to do?

Who am I? 
Where am I? 
What am I supposed to be doing? 
Hello? Is anyone listening?

Example: You could coordinate the units of our DGX system using MPI

A Good Place to Start: MPI Broadcasting

MPI_Bcast( array, count, type, src, MPI_COMM_WORLD );

Address of data to send from if you are the src node; Address of the data to receive into if you are not

# elements

MPI_CHAR
MPI_INT
MPI_LONG
MPI_FLOAT
MPI_DOUBLE

rank of the CPU doing the sending

Broadcast

src node

Both the sender and receivers need to execute MPI_Bcast – there is no separate receive function
This is our heat transfer equation from before. Clearly, every CPU will need to know this value.

\[
\Delta T_i = \left( \frac{k}{\rho C} \right) \left( \frac{T_{i+1} - 2T_i + T_{i-1}}{(\Delta x)^2} \right) \Delta t
\]

```c
int numCPUs;
int me;
float k_over_rho_c;  // the BOSS node will know this value, the others won't (yet)
#define BOSS 0
MPI_Comm_size( MPI_COMM_WORLD, &numCPUs ); // how many are in this communicator
MPI_Comm_rank( MPI_COMM_WORLD, &me );   // which one am I?

if( me == BOSS )
{
    << read k_over_rho_c from the data file >>
}

MPI_Bcast( &k_over_rho_c, 1, MPI_FLOAT, BOSS, MPI_COMM_WORLD ); // send if BOSS, and receive if not
```

Confused? Look at this Diagram

Both the sender and receivers need to execute \texttt{MPI\_Bcast} – there is no separate receive function.

Node \#BOSS:

\texttt{MPI\_Bcast( \&k\_over\_rho\_c, 1, MPI\_FLOAT, BOSS, MPI\_COMM\_WORLD );} // send if BOSS, and receive if not

All Nodes that are not \#BOSS:

\texttt{Executable code} \quad \text{\& \ k\_over\_rho\_c (being set)}

\texttt{Executable code} \quad \text{\& \ k\_over\_rho\_c (being set)}

\texttt{Executable code} \quad \text{\& \ k\_over\_rho\_c (being set)}

\texttt{Executable code} \quad \text{\& \ k\_over\_rho\_c (being set)}

\texttt{Executable code} \quad \text{\& \ k\_over\_rho\_c (being set)}
How Does this Work?
Think Star Trek Wormholes!

MPI_Send( array, numToSend, type, dst, tag, MPI_COMM_WORLD );

Sending Data from One Source CPU to One Destination CPU

Rules:

• One message from a specific src to a specific dst cannot overtake a previous message from the same src to the same dst.

• MPI_Send( ) blocks until the transfer is far enough along that array can be destroyed or re-used.

• There are no guarantees on order from different src’s.
**Receiving Data in a Destination CPU from a Source CPU**

```c
MPI_Recv( array, maxCanReceive, type, src, tag, MPI_COMM_WORLD, &status );
```

**Rules:**

- The receiver blocks waiting for data that matches what it declarations to be looking for.
- One message from a specific `src` to a specific `dst` cannot overtake a previous message from the same `src` to the same `dst`.
- There are no guarantees on the order from different `src`'s.
- The order from different `src`'s could be implied in the `tag`.
- `status` is type `MPI_Status` – the "&status" can be replaced with `MPI_STATUS_IGNORE`.

**Example**

```c
int numCPUs;
int me;
#define MYDATA_SIZE 128
char mydata[ MYDATA_SIZE ];
#define BOSS 0
MPI_Comm_size( MPI_COMM_WORLD, &numCPUs );
MPI_Comm_rank( MPI_COMM_WORLD, &me );
if( me == BOSS ) // the primary
{
    for( int dst = 0; dst < numCPUs; dst++ )
    {
        if( dst != BOSS )
        {
            char *InputData = "Hello, Beavers!";
            MPI_Send( InputData, strlen(InputData)+1, MPI_CHAR, dst, 'B', MPI_COMM_WORLD );
        }
    }
}
else // a secondary
{
    MPI_Recv( myData, MYDATA_SIZE, MPI_CHAR, BOSS, 'B', MPI_COMM_WORLD, MPI_STATUS_IGNORE );
    printf( " '%s' from rank # %d\n", in, me );
}
```

You are highly discouraged from sending to yourself. Because both the send and receive are capable of blocking, the result could be deadlock.
How does MPI let the Sender perform an MPI_Send( ) even if the Receivers are not ready to MPI_Recv( )?

MPI_Send( ) blocks until the transfer is far enough along that the array can be destroyed or re-used.
You typically don’t send the entire workload to each dst – you just send part of it, like this:

```c
#define NUMELEMENTS ????
int numCPUs;
int me;
#define BOSS 0
MPI_Comm_size( MPI_COMM_WORLD, &numCPUs );
MPI_Comm_rank( MPI_COMM_WORLD, &me );
int localSize = NUMELEMENTS / numCPUs; // assuming it comes out evenly
float *myData = new float [ localSize ];

if( me == BOSS ) // the sender
{
    float *InputData = new float [ NUMELEMENTS ];
    << read the full input data into InputData from disk >>
    for( int dst = 0; dst < numCPUs; dst++ )
    {
        if( dst != BOSS )
        {
            MPI_Send( &InputData[dst*localSize], localSize, MPI_FLOAT, dst, 0, MPI_COMM_WORLD );
        }
    }
}
else // a receiver
{
    MPI_Recv( myData, localSize, MPI_FLOAT, BOSS, 0, MPI_COMM_WORLD, MPI_STATUS_IGNORE );
    // do something with this subset of the data
}
```
In Distributed Computing, You Often Hear About These Design Patterns

- **Broadcast**
  - Central node sends data to all other nodes.

- **Scatter**
  - Data sent from a single source to multiple destinations.

- **Gather**
  - Data collected from multiple sources to a single destination.

Scatter and Gather Usually Go Together

Note surprisingly, this is referred to as Scatter/Gather
MPI Scatter

Take a data array, break it into equal portions, and send it to each CPU.

```
MPI_Scatter( snd_array, snd_count, snd_type, rcv_array, rcv_count, rcv_type, src, MPI_COMM_WORLD );
```

- The total large array to split up
- Local array to store this processor's piece in
- # elements to send per-processor
- # elements to receive per-processor
- MPI_CHAR
- MPI_INT
- MPI_LONG
- MPI_FLOAT
- MPI_DOUBLE

Both the sender and receivers need to execute MPI_Scatter. There is no separate receive function.

MPI Gather

```
MPI_Gather( snd_array, snd_count, snd_type, rcv_array, rcv_count, rcv_type, dst, MPI_COMM_WORLD );
```

- The total large array to put the pieces back into
- Local array that this processor is sending back
- # elements to return per-processor
- # elements to send back per-processor
- MPI_CHAR
- MPI_INT
- MPI_LONG
- MPI_FLOAT
- MPI_DOUBLE

Both the sender and receivers need to execute MPI_Gather. There is no separate receive function.
Remember This? It’s Baaaaaack as a complete Scatter/Gather Example

The Compute : Communicate Ratio still applies, except that it is even more important now because there is much more overhead in the Communicate portion.

This pattern of breaking a big problem up into pieces, sending them to different CPUs, computing on the pieces, and getting the results back is very common. That’s why MPI has its own scatter and gather functions.

---

heat.cpp, I

```c
#include <stdio.h>
#include <math.h>
#include <mpi.h>

const float RHO = 8050.;
const float C   = 0.466;
const float K   = 20.;
float k_over_rho_c = K / (RHO*C); // units of m²/sec
// K / (RHO*C) = 5.33x10^-6 m²/sec
NOTE: this cannot be a const!

const float DX    = 1.0;
const float DT    = 1.0;

#define BOSS 0
#define NUMELEMENTS (8*1024*1024)
#define NUM_TIME_STEPS 4
#define DEBUG false

float * NextTemps; // per-processor array to hold computer next-values
int NumCpus; // total # of cpus involved
int PPSSize; // per-processor local array size
float * PPTemps; // per-processor local array temperature data
float * TempData; // the overall NUMELEMENTS-big temperature data

void DoOneTimeStep( int );
```
int main( int argc, char *argv[] )
{
    MPI_Init( &argc, &argv );
    int me;  // which one I am
    MPI_Comm_size( MPI_COMM_WORLD, &NumCpus );
    MPI_Comm_rank( MPI_COMM_WORLD, &me );
    // decide how much data to send to each processor:
    PPSize = NUMELEMENTS / NumCpus;  // assuming it comes out evenly
    PPTemps = new float [PPSize];  // all processors now have this uninitialized Local array
    NextTemps = new float [PPSize];  // all processors now have this uninitialized local array too
    // broadcast the constant:
    MPI_Bcast( (void *)&k_over_rho_c, 1, MPI_FLOAT, BOSS, MPI_COMM_WORLD );

    if( me == BOSS )  // this is the data-creator
    {
        TempData = new float [NUMELEMENTS];
        for( int i = 0; i < NUMELEMENTS; i++ )
            TempData[ i ] = 0.;
        TempData[NUMELEMENTS/2] = 100.;
    }
    MPI_Scatter( TempData, PPSize, MPI_FLOAT, PPTemps, PPSize, MPI_FLOAT, BOSS, MPI_COMM_WORLD );
// all the PPTemps arrays have now been filled
// do the time steps:
double time0 = MPI_Wtime();
for( int steps = 0; steps < NUM_TIME_STEPS; steps++ )
{
    // do the computation for one time step:
    DoOneTimeStep( me );

    // ask for all the data:
#ifdef WANT_EACH_TIME_STEPS_DATA
    MPI_Gather( PPTemps, PPSize, MPI_FLOAT, TempData, PPSize, MPI_FLOAT,
                BOSS, MPI_COMM_WORLD );
#endif
#endif
}

#ifndef WANT_EACH_TIME_STEPS_DATA
    MPI_Gather( PPTemps, PPSize, MPI_FLOAT, TempData, PPSize, MPI_FLOAT,
                BOSS, MPI_COMM_WORLD );
#endif

double time1 = MPI_Wtime();

if( me == BOSS )
{
    double seconds = time1 - time0;
    double performance =
        (double)NUM_TIME_STEPS * (double)NUMELEMENTS / seconds / 1000000.;
    // mega-elements computed per second
    fprintf( stderr, "%3d, %10d, %8.2lf
", NumCpus, NUMELEMENTS, performance );
}

MPI_Finalize( );
return 0;
DoOneTimeStep, I

void DoOneTimeStep( int me )
{
    MPI_Status status;

    // send out the left and right end values:
    // (the tag is from the point of view of the sender)
    if( me != 0 ) // i.e., if i'm not the first group on the left
    {
        // send my PPTemps[0] to me-1 using tag 'L'
        MPI_Send( &PPTemps[0], 1, MPI_FLOAT, me-1, 'L', MPI_COMM_WORLD);
        if( DEBUG ) fprintf( stderr, "%3d sent 'L' to %3d
", me, me-1 );
    }

    if( me != NumCpus-1 ) // i.e., not the last group on the right
    {
        // send my PPTemps[PPSize-1] to me+1 using tag 'R'
        MPI_Send( &PPTemps[PPSize-1], 1, MPI_FLOAT, me+1, 'R', MPI_COMM_WORLD);
        if( DEBUG ) fprintf( stderr, "%3d sent 'R' to %3d
", me, me+1 );
    }
}

DoOneTimeStep, II

float left = 0.;
float right = 0.;

if( me != 0 ) // i.e., if i'm not the first group on the left
{
    // receive my "left" from me-1 using tag 'R'
    MPI_Recv( &left, 1, MPI_FLOAT, me-1, 'R', MPI_COMM_WORLD, &status);
    if( DEBUG ) fprintf( stderr, "%3d received 'R' from %3d
", me, me-1 );
}

if( me != NumCpus-1 ) // i.e., not the last group on the right
{
    // receive my "right" from me+1 using tag 'L'
    MPI_Recv( &right, 1, MPI_FLOAT, me+1, 'L', MPI_COMM_WORLD, &status);
    if( DEBUG ) fprintf( stderr, "%3d received 'L' from %3d
", me, me+1 );
}
In the above drawing, Compute : Communicate is 4 : 2
DoOneTimeStep, III

// first element on the left (0):
{
    float dtemp = ( k_over_rho_c * 
                   ( left - 2.*PPTemps[0] + PPTemps[1] ) / ( DX*DX ) ) * DT;
    NextTemps[0] = PPTemps[0] + dtemp;
}

// all the nodes in the middle:
for( int i = 1; i < PPSize-1; i++ )
{
    float dtemp = ( k_over_rho_c * 
                   ( PPTemps[i-1] - 2.*PPTemps[i] + PPTemps[i+1] ) / ( DX*DX ) ) * DT;
    NextTemps[i] = PPTemps[i] + dtemp;
}

// last element on the right (PPSize-1):
{
    float dtemp = ( k_over_rho_c * 
                   ( PPTemps[PPSize-2] - 2.*PPTemps[PPSize-1] + right ) / ( DX*DX ) ) * DT;
    NextTemps[PPSize-1] = PPTemps[PPSize-1] + dtemp;
}

DoOneTimeStep, IV

// update the local dataset:

**MPI Reduction**

```
MPI_Reduce( partialResult, globalResult, count, type, operator, dst, MPI_COMM_WORLD );
```

- **Where the partial result is stored on each CPU**
- **Number of elements in the partial result**
- **MPI_Char**
- **MPI_INT**
- **MPI_LONG**
- **MPI_FLOAT**
- **MPI_DOUBLE**
- **MPI_MIN**
- **MPI_MAX**
- **MPI_SUM**
- **MPI_PROD**
- **MPI_MINLOC**
- **MPI_MAXLOC**
- **MPI_BAND**
- **MPI_BOR**
- **MPI_LAND**
- **MPI_LOR**
- **MPI_BXOR**
- **MPI_LXOR**
- **Who is given the final answer**

---

**MPI Reduction Example**

```c
// gratuitous use of a reduce -- average all the temperatures:

float partialSum = 0.;
for( int i = 0; i < PPSize; i++ )
    partialSum += PPTemps[ i ];

float globalSum = 0.;
MPI_Reduce( &partialSum, &globalSum, 1, MPI_FLOAT, MPI_SUM, BOSS, MPI_COMM_WORLD );

if( me == BOSS )
    fprintf( stderr, "Average temperature = %f\n", globalSum/(float)NUMELEMENTS );
```

---

**Both the sender and receivers need to execute **MPI_Reduce**. There is no separate receive function.**
MPI Barriers

All CPUs must execute the call to MPI_Barrier() before any of the CPUs can move past it. That is, each CPU's MPI_Barrier() blocks until all CPUs execute a call to MPI_Barrier().

Distributed Processors:

0 1 2 3 4 5

Time

Barrier

MPI Derived Types

Idea: In addition to types MPI_INT, MPI_FLOAT, etc., allow the creation of new MPI types so that you can transmit an "array of structures".

Reason: There is significant overhead with each transmission. Better to send one entire array of structures instead of sending several arrays separately.

MPI_Type_create_struct( count, blocklengths, displacements, types, datatype );

struct point {
    int pointSize;
    float x, y, z;
};

MPI_Datatype MPI_POINT;
int blocklengths[ ] = { 1, 1, 1, 1 };
int displacements[ ] = { 0, 4, 8, 12 };
MPI_type types[ ] = { MPI_INT, MPI_FLOAT, MPI_FLOAT, MPI_FLOAT };

MPI_Type_create_struct( 4, blocklengths, displacements, types, &MPI_POINT);

You can now use MPI_POINT everywhere you could have used MPI_INT, MPI_FLOAT, etc.
### MPI Timing

**double MPI_Wtick();**

Returns the resolution of the clock, in seconds.

**double MPI_Wtime();**

Returns the time, in seconds, since "some time in the past".

*Warning: the clocks on the different CPUs are not guaranteed to be synchronized!*

### MPI Status-Checking

Some MPI calls have a `&status` in their argument list. The `status` argument is declared to be of type `MPI_Status`, which is defined like this:

```c
typedef struct _MPI_Status {
    int MPI_SOURCE;
    int MPI_TAG;
    int MPI_ERROR;
} MPI_Status;
```

- `MPI_SOURCE` is the rank of the node who sent this
- `MPI_TAG` is the tag used during the send
- `MPI_ERROR` is the error number that occurred

**Example:**

```c
MPI_Status status;
MPI_Recv( myData, MYDATA_SIZE, MPI_CHAR, BOSS, MPI_ANY_TAG, MPI_COMM_WORLD, &status );
fprintf( stderr, "Tag = %d\n", status.MPI_TAG );
```
## MPI Error Codes

<table>

### Example: Autocorrelation

The Original Signal

![The Original Signal](attachment:image.png)

Invalid keyval has been passed
Invalid keyval failed because memory is exhausted
Invalid base passed to MPI_FREE_MEM
Key longer than MPI_MAX_INFO_KEY
Value longer than MPI_MAX_INFO_VAL
Invalid key passed to MPI_INFO_DELETE
Error in sending process
Invalid port name passed to MPI_COMM_CONNECT
Invalid service name passed to MPI_ERROR_UNPUBLISH_NAME
Invalid service name passed to MPI LOOKUP_NAME
Invalid time argument
Invalid size argument
Invalid shape argument
Invalid info argument
Invalid wildcard argument
Invalid wildcard argument
Conflicting access to window
Wrong synchronization of IMA calls

Invalid file handle
Collective argument not identified on all processes, or collective routines called in a different order by different processes
Error related to the attribute passed to MPI_FILE_OPEN
Unsupported data type passed to MPI_FILE_SET_VIEW
Unsupported operation, such as opening or accessing a file which supports sequential access only
File does not exist
File exists
Invalid file name (e.g., path name too long)
Permission denied
Not enough space
Quota exceeded
Insufficient file descriptor
File operation could not be completed, as the file is currently open by some process
Conversion functions could not be registered because a data representation identifier that was already defined was passed to MPI_REGISTER_DATAREP
An error occurred in a user supplied data conversion function
Other I/O error
Last error code

Autocorrelation – More than Just a Scatter

Divide NUMELEMENTS into pieces for the NumCpus
(this is what MPI_Scatter does)

But, in the Autocorrelation case, we need MAXSHIFTS more data values for each CPU

Autocorrelation – How the Shifting Works

Shift = 0

Shift = 1

Shift = 2

Shift = 3

Shift = MAXSHIFTS-1
