Parallel Programming using OpenMP

Oregon State University
Mike Bailey
mjb@cs.oregonstate.edu

OpenMP Multithreaded Programming

- OpenMP stands for "Open Multi-Processing"
- OpenMP is a multi-vendor (see next page) standard to perform shared-memory multithreading
- OpenMP is both compiler-directive- and library-based
- OpenMP threads share a single executable, a single global memory, and a single heap (malloc, new)
- Each OpenMP thread has its own stack (function arguments, function return address, local variables)
- Using OpenMP usually requires no dramatic code changes
- OpenMP probably gives you the biggest multithread benefit per amount of work you have to put in to using it

Much of your use of OpenMP will be accomplished by issuing C/C++ "pragmas" to tell the compiler how to build the threads into your executable, like this:

#pragma omp directive [clause]

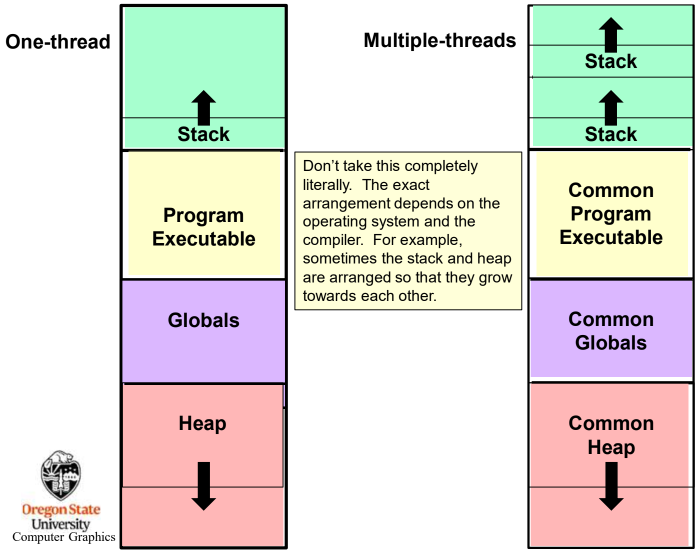
Who is in the OpenMP Consortium?

What OpenMP Isn't:

- OpenMP doesn't check for data dependencies, data conflicts, deadlocks, or race conditions. You are responsible for avoiding those yourself
- OpenMP doesn't check for non-conforming code sequences (we'll talk about what this means)
- OpenMP doesn't guarantee ***identical*** behavior across vendors or hardware, or even between multiple runs on the same vendor's hardware
- OpenMP doesn't guarantee the ***order*** in which threads execute, just that they do execute
- OpenMP is not overhead-free
- OpenMP does not prevent you from writing code that triggers cache performance problems (such as in false-sharing), in fact, *it makes it really easy*

We will get to "false sharing" in the cache notes

Memory Allocation in a Multithreaded Program



Oregon State University Computer Graphics

Using OpenMP on Linux

```
g++ -o proj proj.cpp -lm -fopenmp
```

Using OpenMP in Microsoft Visual Studio

1. Go to the Project menu ⟶ Project Properties
2. Change the setting Configuration Properties ⟶ C/C++ ⟶ Language ⟶ OpenMP Support to **"Yes (/openmp)"**

If you are using Visual Studio and get a compile message that looks like this:
1>c1xx: error C2338: two-phase name lookup is not supported for C++/CLI, C++/CX, or OpenMP; use /Zc:twoPhase-
then do this:

1. Go to "Project Properties"→ "C/C++" → "Command Line"
2. Add **/Zc:twoPhase-** in "Additional Options" in the bottom section
3. Press OK

Oregon State University Computer Graphics

Seeing if OpenMP is Supported on Your System

```
#ifdef _OPENMP
    fprintf( stderr, "OpenMP release %d is supported here\n", _OPENMP );
#else
    fprintf( stderr, "OpenMP is not supported here – sorry!\n" );
    return 1;
#endif
```

Printing _*OPENMP* gives you a year and month of the OpenMP release that you are using

To get the OpenMP version number from the year and month, check here:

OpenMP 5.0 – November 2018
OpenMP 4.5 – November 2015
OpenMP 4.0 – July 2013
OpenMP 3.1 – July 2011
OpenMP 2.0 – March 2002
OpenMP 1.0 – October 1998

- By default, flip uses g++ 11.4, which uses OpenMP version 4.5
- Visual Studio 2022 uses OpenMP 2.0

Oregon State University Computer Graphics

Numbers of OpenMP threads

How to specify how many OpenMP threads you want to have available:

```
omp_set_num_threads( num );
```

Asking how many cores this program has access to:

```
num = omp_get_num_procs( );
```

Actually returns the number of hyperthreads, not the number of *physical* cores

Setting the number of available threads to the exact number of cores available:

```
omp_set_num_threads(    omp_get_num_procs( )    );
```

Asking how many OpenMP threads this program is using right now:

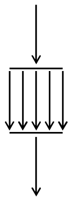
```
num = omp_get_num_threads( );
```

Asking which thread number this one is:

```
me = omp_get_thread_num( );
```

Oregon State University Computer Graphics

Creating an OpenMP Team of Threads



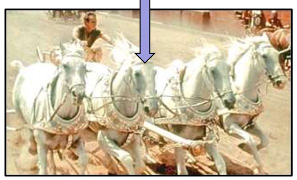
```
#pragma omp parallel default(none)
{
        . . .
}
```

This creates a team of threads

Each thread then executes all lines of code in this block.

Think of it this way:

#pragma omp parallel default(none)



Oregon State University Computer Graphics

The OpenMP Thread Team Prints a Friendly Message

```
#include <stdio.h>
#include <omp.h>
int
main( )
{
        omp_set_num_threads( 8 );
        #pragma omp parallel default(none)
        {
            printf( "Hello, World, from thread #%d ! \n" , omp_get_thread_num( )  );
        }
        return 0;
}
```

Hint: run it several times in a row. What do you see? Why?

Oregon State University Computer Graphics

Uh-oh…

First Run	Second Run
Hello, World, from thread #6 !	Hello, World, from thread #0 !
Hello, World, from thread #1 !	Hello, World, from thread #7 !
Hello, World, from thread #7 !	Hello, World, from thread #4 !
Hello, World, from thread #5 !	Hello, World, from thread #6 !
Hello, World, from thread #4 !	Hello, World, from thread #1 !
Hello, World, from thread #3 !	Hello, World, from thread #3 !
Hello, World, from thread #2 !	Hello, World, from thread #5 !
Hello, World, from thread #0 !	Hello, World, from thread #2 !

Third Run	Fourth Run
Hello, World, from thread #2 !	Hello, World, from thread #1 !
Hello, World, from thread #5 !	Hello, World, from thread #3 !
Hello, World, from thread #0 !	Hello, World, from thread #5 !
Hello, World, from thread #7 !	Hello, World, from thread #2 !
Hello, World, from thread #1 !	Hello, World, from thread #4 !
Hello, World, from thread #3 !	Hello, World, from thread #7 !
Hello, World, from thread #4 !	Hello, World, from thread #6 !
Hello, World, from thread #6 !	Hello, World, from thread #0 !

There is no guarantee of thread execution order!

Oregon State University Computer Graphics

Creating OpenMP Threads to Process Loop Passes

```
#include <omp.h>

. . .
omp_set_num_threads( NUMT );
. . .
#pragma omp parallel for default(none)
for( int i = 0; i < arraySize; i++ )
{
        . . .
}
```

The code starts out executing in a single thread

This sets how many threads will be created. It doesn't create them yet; it just says how many will be used the next time you ask for them.

Here we ask for them. This creates a team of threads and divides the for-loop passes up among those threads

There is an **"implied barrier"** at the end where each thread waits until all threads are done, then the code continues in a single thread

This tells the compiler to parallelize the for-loop into multiple threads. Each thread automatically gets its own personal copy of the variable ***i*** because it is defined within the for-loop body.

The **default(none)** directive forces you to explicitly declare all variables declared outside the parallel region to be either private or shared while they are in the parallel region. Variables declared within the for-loop are automatically private.

Oregon State University Computer Graphics

OpenMP for-Loop Rules

#pragma omp parallel for default(none), shared(…), private(…)

for(int index = start ; index terminate condition; index changed)

- The *index* must be an *int* or a *pointer*
- The *start* and *terminate* conditions must have compatible types
- Neither the *start* nor the *terminate* conditions can be changed during the execution of the loop
- The *index* can only be modified by the *changed* expression (i.e., not modified inside the loop itself)
- You cannot use a *break* or a *goto* to get out of the loop
- There can be no inter-loop data dependencies such as:

a[i] = a[i-1] + 1.;

```
a[101] = a[100] + 1.;      // what if this is the last line of thread #0's work?
-----------------------
a[102] = a[101] + 1.;      // what if this is the first line of thread #1's work?
```

Oregon State University Computer Graphics

OpenMP For-Loop Rules

for(index = start ;	index < end index <= end index > end index >= end	;	index++ ++index index-- --index index += incr index = index + incr index = incr + index index -= decr index = index - decr	)

Oregon State University Computer Graphics

What to do about Variables Declared Before the for-loop Starts?

```
float x = 0.;
#pragma omp parallel for …
for( int i = 0; i < N; i++ )
{
        x = (float) i;
        float y = x*x;
        << more code… >
}
```

i and **y** are automatically *private* because they are defined within the loop.

Good practice demands that **x** be explicitly declared to be shared or private!

private(x)
Means that each thread will get its own version of the variable

shared(x)
Means that all threads will share a common version of the variable

default(none)
I recommend that you include this in your OpenMP for-loop directive. This will force you to explicitly flag all of your externally-declared variables as *shared* or *private*. Don't make a mistake by leaving it up to the default!

Example:
#pragma omp parallel for default(none), private(x)

Oregon State University Computer Graphics

For-loop "Fission"

Because of the loop dependency, this whole thing is not parallelizable:

```
x[ 0 ] = 0.;
y[ 0 ] *= 2.;
for( int i = 1; i < N; i++ )
{
        x[ i ] = x[ i-1 ] + 1.;
        y[ i ] *= 2.;
}
```

But it *can* be broken into one loop that is not parallelizable, plus one that is:

```
x[ 0 ] = 0.;
for( int i = 1; i < N; i++ )
{
        x[ i ] = x[ i-1 ] + 1.;
}

#pragma omp parallel for shared(y)
for( int i = 0; i < N; i++ )
{
        y[ i ] *= 2.;
}
```

Oregon State University Computer Graphics

For-loop "Collapsing"

Uh-oh, which for-loop do you put the #pragma on?

```
for( int i = 1; i < N; i++ )
{
        for( int j = 0; j < M; j++ )
        {
                . . .
        }
}
```

Ah-ha – trick question. You put it on both!

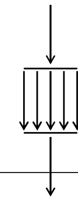
How many for-loops to collapse into one loop

```
#pragma omp parallel for collapse(2)
for( int i = 1; i < N; i++ )
{
        for( int j = 0; j < M; j++ )
        {
                . . .
        }
}
```

Oregon State University Computer Graphics

Single Program Multiple Data (SPMD) in OpenMP

```
#define NUM        1000000
float A[NUM], B[NUM], C[NUM];
. . .
int total = omp_get_num_threads( );
#pragma omp parallel default(none),shared(total)
{
    int me = omp_get_thread_num( );
    DoWork( me, total );
}
```



```
void  DoWork( int m, int t )
{
        int first = NUM * m / t;
        int last = NUM * (m+1)/t   -   1;
        for( int i = first; i <= last; i++ )
        {
                C[ i ] = A[ i ] * B[ i ];
        }
}
```

Oregon State University Computer Graphics

OpenMP Allocation of Work to Threads

Static Threads
- All work is allocated and assigned at runtime

Dynamic Threads
- The pool is statically assigned some of the work at runtime, but not all of it
- When a thread from the pool becomes idle, it gets a new assignment
- "Round-robin assignments"

OpenMP Scheduling

schedule(static [,chunksize])
schedule(dynamic [,chunksize])
Defaults to static
chunksize defaults to 1

Oregon State University Computer Graphics

OpenMP Allocation of Work to Threads

#pragma omp parallel for default(none),schedule(static,chunksize)
for(int index = 0 ; index < 12 ; index++)

Static,1
0 0,3,6,9
1 1,4,7,10
2 2,5,8,11

chunksize = 1
Each thread is assigned one iteration, then the assignments start over

Static,2
0 0,1,6,7
1 2,3,8,9
2 4,5,10,11

chunksize = 2
Each thread is assigned two iterations, then the assignments start over

Static,4
0 0,1,2,3
1 4,5,6,7
2 8,9,10,11

chunksize = 4
Each thread is assigned four iterations, then the assignments start over

Think of dealing for-loop passes to threads the same way as dogs deal cards ☺

Oregon State University Computer Graphics

Arithmetic Operations Among Threads – A Problem

21

```
float sum = 0.;
#pragma omp parallel for default(none), shared(sum)
 for( int i = 0; i < N; i++ )
{
      float myPartialSum = …

      sum = sum + myPartialSum;
}
```

• There is no guarantee when each thread will execute this line

• There is not even a guarantee that each thread will finish this line before some other thread interrupts it. (Remember that each line of code usually generates multiple lines of assembly.)

• This is non-deterministic !

Assembly code:

```
Load sum
Add   myPartialSum
Store sum
```

What if the scheduler decides to switch threads right here?

Oregon State University Computer Graphics

Conclusion: Don't do it this way!

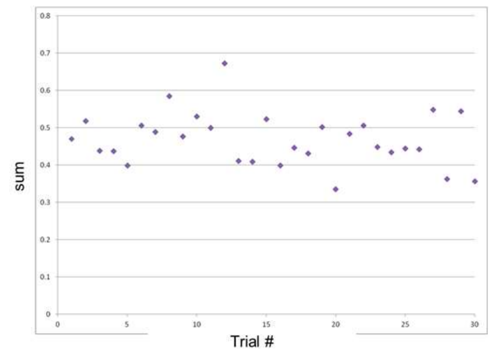
mjb – April 9, 2024

Here's a trapezoid integration example.

22

The partial sums are added up, as shown on the previous page.
The integration was done 30 times.
The answer is supposed to be exactly 2.
None of the 30 answers is even close.
And not only are the answers *bad*, but they are not even consistently *bad*!

0.469635	0.398893
0.517984	0.446419
0.438868	0.431204
0.437553	0.501783
0.398761	0.334996
0.506564	0.484124
0.489211	0.506362
0.584810	0.448226
0.476670	0.434737
0.530668	0.444919
0.500062	0.442432
0.672593	0.548837
0.411158	0.363092
0.408718	0.544778
0.523448	0.356299



Oregon State University Computer Graphics

Don't do it this way! We'll talk about how to do it correctly in the Trapezoid Integration noteset.

mjb – April 9, 2024

Synchronization

23

Mutual Exclusion Locks (Mutexes)

*omp_init_lock(omp_lock_t *);*
*omp_set_lock(omp_lock_t *);* — Blocks if the lock is not available. Then sets it and returns when it is available
*omp_unset_lock(omp_lock_t *);*
*omp_test_lock(omp_lock_t *);* — If the lock is not available, returns 0. If the lock is available, sets it and returns !0

(*omp_lock_t* is really an array of 4 unsigned chars)

Critical sections

#pragma omp critical
Restricts execution to one thread at a time

#pragma omp single
Restricts execution to a single thread ever

Barriers

#pragma omp barrier
Forces each thread to wait here until all threads arrive

Oregon State University Computer Graphics

(Note: there is an implied barrier after parallel for loops and OpenMP sections, unless the *nowait* clause is used)

mjb – April 9, 2024

Synchronization Example

24

```
omp_lock_t          Sync;
. . .
omp_init_lock( &Sync );

. . .
```

Thread #0:	Thread #1:
omp_set_lock(&Sync);	**omp_set_lock(&Sync);**
<< code that needs the mutual exclusion >>	<< code that needs the mutual exclusion >>
omp_unset_lock(&Sync);	**omp_unset_lock(&Sync);**

Oregon State University Computer Graphics

mjb – April 9, 2024

Synchronization Example

```
omp_lock_t            Sync;
. . .
omp_init_lock( &Sync );

. . .
```

Thread #0:

```
while(  omp_test_lock( &Sync ) == 0  )
{
            DoSomeUsefulWork_0( );
}
```

Thread #1:

```
while(  omp_test_lock( &Sync ) == 0  )
{
            DoSomeUsefulWork_1( );
}
```

Oregon State University Computer Graphics

Single-thread-execution Synchronization

#pragma omp single

Restricts execution to a single thread ever. This is used when an operation only makes sense for one thread to do. Reading data from a file is a good example.

Oregon State University Computer Graphics

Creating Sections of OpenMP Code

Sections are independent blocks of code, able to be assigned to separate threads if they are available.

```
#pragma omp parallel sections
{
      #pragma omp section
      {
            Task 1
      }
      #pragma omp section
      {
            Task 2
      }
}
```

(Note: there is an **implied** barrier after parallel for loops and OpenMP sections, unless the *nowait* clause is used)

Oregon State University Computer Graphics

A Functional Decomposition Sections Example

```
omp_set_num_threads( 3 );

#pragma omp parallel sections
{
            #pragma omp section
            {
                  Watcher( );
            }

            #pragma omp section
            {
                  Animals( );
            }

            #pragma omp section
            {
                  Plants( );
            }
}   // implied barrier -- all functions must return to get past here
```

Oregon State University Computer Graphics

A Potential OpenMP/Visual Studio Compiler Problem

If you print to standard error (stderr) from inside a for-loop, like I do, then you think that you need to include *stderr* in the shared list because, well, the loops share it:

#pragma omp parallel for default(none) shared(a,b,stderr)

This turns out to be true for ***g++/gcc only***.

If you are using Visual Studio, then ***do not*** **include stderr in the list**. If you do, you will get this error:

1>Y:\CS575\SQ22\robertw5-01\Project1\Project1.cpp(113,98): error C2059: syntax error: '('

This is because:
- In g++/gcc, stderr is a *variable*
- In Visual Studio, stderr is a *defined macro*
