PILOT CAR
FOLLOW ME
To a Better Grade

Why Are These Notes Here?

These notes are here to:
1. Help you setup and run your projects
2. Help you get the data you collect in the right format for submission
3. Help you get a better grade by doing all of this correctly!

How We Will Be Doing Timing

In this class, we don’t want to just implement – we want to characterize performance. What speed-ups do we see, and why do we see them? How do we generalize that to other types of problems? What insights does this give us?

So, as part of your project assignments, you will be doing a lot of timing to determine program speed-ups.

How Reliable is the Timing?

This way of timing measures wall-clock time, which is really what we want to know in a parallel environment, not CPU time.

However, this puts you at the mercy of the other users on the system. If you are on one of our public systems (e.g., flip), I advise you to check the system load to see how much off your wall-clock time measurement will be due to the competition from other users. Use the Linux uptime command:

```
flip01 34% uptime
```

These three numbers represent total CPU load averages for the last 1, 5, and 15 minutes respectively. If the CPU load average is greater than the number of CPUs, then each CPU is over-burdened.

Clearly you want these numbers, especially the 1-minute one, to be as small as possible when you run your test. If they are “big”, you might want to ssh to other systems (flip01, flip02, flip03, …) to see if you can find a better place to run, or try again later.

How Reliable is the Timing? A Useful Trick!

I like to check the consistency of the timing by computing both peak speed and average speed and seeing how close they are:

```
double maxmflops = 0.;
double summflops = 0.;
for( int t = 0; t < NUMTRIES; t++ ) {
double time0 = omp_get_wtime();
#pragma omp parallel for
for( int i = 0; i < ARRAYSIZE; i++ ) {
    C[i] = A[i] * B[i];
}
double time1 = omp_get_wtime();
double mflops = (double)ARRAYSIZE/(time1-time0)/1000000.;
summflops += mflops;
if( mflops > maxmflops )
    maxmflops = mflops;
}
printf( "     Peak Performance = %8.2lf MFLOPS
", maxmflops );
printf( "Average Performance = %8.2lf MFLOPS
", summflops/(double)NUMTRIES );
```

This is a reliable result:
```
Peak Performance = 1183.31 MFLOPS
Average Performance = 1141.41 MFLOPS
```

This is an unreliable result:
```
Peak Performance = 627.39 MFLOPS
Average Performance = 294.86 MFLOPS
```
If you are on Linux and have access to the Intel compiler, icpc, don’t use it unless we tell you to! (icpc is so good that it often does optimizations that undermine the very things you are testing.)

Use g++. The compilation sequences are:

On Linux, the typical compile sequence for files that use OpenMP is:

```
g++   -o   proj proj.cpp   -O3   -lm   -fopenmp
```

icpc -o   proj proj.cpp   -O3   -lm   -openmp -align  -qopt-report=3  -qopt-report-phase=vec

Note that OpenMP should always be included because we are using OpenMP calls for timing.

If you are on Linux and have access to the Intel compiler, icpc, don’t use it unless we tell you to! (icpc is so good that it often does optimizations that undermine the very things you are testing.)

Use g++. The compilation sequences are:

Note that the second character in the 3-character sequence “-lm” is an ell, i.e., a lower-case L.

This is how you link in the Math library.

• Most of these projects will require you to submit graphs. You can prepare the graphs any way you want, except for drawing them by hand. (The Excel Scatter-with-Smooth-Lines-and-Markers works well.) So that we can easily look at each other’s graphs, please follow the convention that up is faster. That is, do not plot seconds on the Y axis because then “up” would mean “slower”. Instead, plot something like Speedup or MFLOPS or frames-per-second.

• I expect the graphs to show off your scientific literacy — that is, I expect axes with numbers, labels, and units. If there are multiple curves on the same set of axes, I expect to be able to easily tell which curve goes with which quantity. After all, there is a reason this major is called Computer Science. Not doing this makes your project unacceptable for grading.

You lose points if you don’t do it this way.

Diverting to a File

We all have a tendency to want to write our performance results out using printf (or cout) so that we can see them on the screen. That’s fine. But, then we want to get those results into a file. You could mess with file I/O, or you could use a divert on the command line.

If you are currently running your program like this:

```
./proj01
```

and it prints to the standard output screen via printf or cout, then running it like this:

```
./proj01  >  output.csv
```

will write your results into the file output.csv

(If you do it a second time, you will probably have to remove the previous output.csv first.) You can also divert the entire output (standard out and standard error) of a looping script:

```
loop.bash >&  output
```

You can avoid all that copying and pasting by using an Excel feature called Pivot Tables! See the Pivot Table noteset.
Then, sweep over the entire table.

Then, select Copy, and then insert it into one of the scatterplot options.

I like this one:

Here's the Graph that Excel Produced from this Data

Adding Annotation

To transpose the sense of the graph (which you also need to do), right-click on the border of the graph and then click on "Select Data". Then click on "Switch Row/Column".

You might have to adjust the X axis number maximum and minimum.
Adding Annotation

I like using PowerPoint for this, but you need to do it somewhere to get the proper graph into your project report.

It's the Same Data, but Each Graph Gives You a Different Insight into what the Data is Telling You

This Data is actually a 3D Surface Plot – The 2D Graphs are actually sets of 2D slices through the 3D Surface

Making Graphs

When we plot, we will all put execution performance on the Y axis (as opposed to putting elapsed time on the Y axis). Thus, as far as performance goes, up will mean “good”. So, for example:

As you can tell, these performance measurements will be far more intelligible when examined as a graph than as raw numbers. Thus, you are expected to have access to a good automated graphing package. If you don’t have one or can’t get access to one – go get one!

Hand-drawn graphs, whether analog or digital, will not be accepted for your assignments.

You will also need a word processor, with a way to import your tables and graphs, and with a way to turn that document into PDF.

Making Graphs

Setting up Your Benchmarks to run from Scripts:

There are always advantages to not hardcoding constants into the middle of your program and, instead, setting them with a #define at the top where you can find that value and change it easily, like this:

```c
#include <stdio.h>
#include <math.h>

#ifndef NUMT
#define NUMT 2
#endif

#ifndef NUMS
#define NUMS 32
#endif
```

Then, in the C or C++ program, all you have to do is use NUMT to set the number of threads, like this:

```c
omp_set_num_threads( NUMT );
```

But, the use of the #ifdef/#endif construct has other advantages. It lets you either run this as a standalone program or run many occurrences of the program from a script.
In our project assignments, you will run benchmarks, that is, you will try your application using several different combinations of parameters. Setting these combinations by hand inside your program one-by-one is a time-consuming pain.

Your time is more valuable than that. Try doing it from a script.

In most C and C++ compilers, there is some mechanism to set a #define from outside the program. Many of them use the –D construct on the command line:

```
#!/bin/bash
# number of threads:
for t in 1 2 4 6 8
do
echo NUMT = $t
g++ -DNUMT=$t prog.cpp -o prog -lm -fopenmp
./prog
done
done
```

Then, in the C or C++ program, all you have to do is use NUMT. For example:

```c
omp_set_num_threads( NUMT );
```

This lets you automatically run your program 5 times with 1, 2, 4, 6, and 8 threads.

---

Setting up Your Benchmarks to run from Scripts:
Method #1 -- the #define Approach

You can also test multiple parameters from the same script by nesting the loops. This one is done using Bash Shell (bash):

```
#!/bin/bash
# number of threads:
for t in 1 2 4 6 8
do
echo NUMT = $t
  # number of subdivisions:
  for s in 2  4  8  16  32  64  128  256  512  1024  2048  3072  4096
done
done
g++ -DNUMS=$s -DNUMT=$t prog.cpp -o prog -lm -fopenmp
./prog
```

Or, in C Shell (csh):

```
#!/bin/csh
# number of threads:
foreach t ( 1 2 4 6 8 )
  echo NUMT = $t
  # number of subdivisions:
  foreach s ( 2  4  8  16  32  64  128  256  512  1024  2048  3072  4096 )
    echo NUMS = $s
g++ -DNUMS=$s -DNUMT=$t prog.cpp -o prog -lm -fopenmp
  ./prog
end
end
```

Or, in Python:

```
import os
for t in [ 1, 2, 4, 6, 8 ]:
  print "NUMT = %d" % t
  for s in [ 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 3072, 4096 ]:
    print "NUMS = %d" % s
    cmd = "g++ -DNUMS=%d -DNUMT=%d prog.cpp -o prog -lm -fopenmp % ( s, t ) "
    os.system( cmd )
    cmd = "/prog"
    os.system( cmd )
```

Setting up Your Benchmarks to run from Scripts:
Method #2 -- the Command Line Arguments Approach

Instead of this:

```
#include <stdio.h>
#include <math.h>
#ifndef NUMT
#define NUMT 8
#endif
#ifndef NUMS
#define NUMS 32
#endif
```

Then, in the C or C++ program, all you have to do is use NUMT to set the number of threads, like this:

```c
omp_set_num_threads( NUMT );
```

But, the use of the #ifdef/#endif construct has other advantages. It lets you either run this as a standalone program or run many occurrences of the program from a script.

When you write in C or C++, your `main` program, which is really a special function call, looks like this:

```
int main( int argc, char *argv[ ] )
{
  ...}
```

These arguments describe what was entered on the command line used to run the program.

The `argc` is the number of arguments (the argument count).
The `argv` is a list of arg character strings that were typed (the argument vector).
The name of the program counts as the 0th argv (i.e., argv[0])

So, for example, when you type

`ls -l`

in a shell, the ls program sees argc and argv filled like this:

```
$ ls -l
argc = 2
argv[0] = "ls"
argv[1] = "-l"
```

argc and argv
So, if NUMT and NUMS are global int variables:

```c
int NUMT = 2;
int NUMS = 32;
```

and you want to set them from the command line, like this:

```bash
./prog 1 64
```

Then, inside your main program, you would say this:

```c
if( argc >= 2 )
    NUMT = atoi( argv[1] );
if( argc >= 3 )
    NUMS = atoi( argv[2] );
```

The if-statements guarantee that nothing bad happens if you forget to type values on the command line.

The `atoi` function converts a string into an integer ("ascii-to-integer"). If you ever need it, there is also an `atof` function for floating-point.

In our project assignments, you will run benchmarks, that is, you will try your application using several different combinations of parameters. Setting these combinations by hand inside your program one-by-one is a time-consuming pain. Your time is more valuable than that. Try doing it from a script.

```bash
#!/bin/bash

g++ prog.cpp -o prog -lm -fopenmp

# number of threads:
for t in 1 2 4 6 8
do
    echo NUMT = $t
    ./prog $t
done
```

This lets you automatically run your program 5 times with 1, 2, 4, 6, and 8 threads.

Or, in Python...

```python
import os

cmd = "g++ prog.cpp -o prog -lm -fopenmp"
for t in [1, 2, 4, 6, 8]:
    print "NUMT = \"$t\"", t
for s in [2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 3072, 4096]:
    cmd = "./prog \"$t \" $s\"
    print "NUMS = \"$s\"", s
os.system( cmd )
```
I Don't Recommend That You Put These Loops in the .cpp Program!

I know what you’re thinking.

You're thinking:

Those scripts are a pain, and I've never done them before. So, I'll just build the iterations through all the parameters into for-loops in the program.

Don’t! I have seen evidence that the first time OpenMP does anything, it also does some one-time setups. This will mess up your timing because your first test will seem slower than it should be and the others will seem faster by comparison.

I recommend you run the program separately for each combination of parameters. (The script code in the previous pages shows that.)

Computing Performance

When computing performance, be sure that the numerator is amount of work done and the denominator is the amount of time it took to do that work. For example, in the Bezier surface example, computing one height is the work done at each node and you have NUMS*NUMS total nodes, so (NUMS*NUMS)/dt is one good way to measure performance.

NUMS, NUMS^2, NUMS/10, and NUMS/10^2 are not good ways to measure performance as they don't reflect the true amount of work done per time.

If you are using ridiculously high values for NUMS, the quantity NUMS^2 might overflow a normal 32-bit int. You can use a long int, or just float each one separately. Instead of (float)(NUMS^2)/dt, you could say (float)NUMS*(float)NUMS/dt

If you are squaring a size number, and are using signed ints, the largest NUMS you can use is:

$\sqrt{2,147,483,647} = 46,340$

If you are squaring a size number, and are using unsigned ints, the largest NUMS you can use is:

$\sqrt{4,294,967,295} = 65,535$

Project Turn-in Procedures

Your project turnins will all be electronic. For all projects:

Your project turnins will be done at http://engr.oregonstate.edu/teach and will consist of:

1. Source files of everything (cpp, .cl, .cuda)
2. A report in PDF format. You can zip everything else if you want, but please leave the PDF as a separate file.

Electronic submissions are due at 23:59:59 on the listed due date.

Your PDF report will include:

1. A title area, including your name, email, project number, and project name.
2. Any tables or graphs to show your results.
3. An explanation of what you did and why it worked the way it did. Your submission will not be considered valid unless you at least attempt to explain why it works the way it does.

Your project will be graded and the score posted to the class web page. Any loss of points will be explained in a Canvas grade comment.

Don't forget that title area! Because I concatenate all the class PDFs together for grading, lack of a name on your project will make it difficult to know who to give this grade to. It will be 5 points off if you forget.

Bonus Days

Projects are due at 23:59:59 on the listed due date, with the following exception:

Each of you has been granted five Bonus Days, which are no-questions-asked 24-hour project extensions which may be applied to any project, subject to the following rules:

1. If the project handout says "No Bonus Days", then no Bonus Days can be used on it. It is due exactly at 23:59:59 on the given due date, no later.
2. No more than two Bonus Days may be applied to any one project
3. Bonus Days cannot be applied to quizzes or tests

To use one or more Bonus Days on a given project:

• You don't need to let me know ahead of time.
• Turn-in promptness is measured by date. Don't worry if teach tells you it's late because it is between 23:30:01 and 23:59:59. But, after 23:59:59 on the posted due date, it's late!
• For any project for which Bonus Days can be used, teach has been instructed to accept your turn-in, no matter when you do it.
• I will run a script to identify the projects that will have Bonus Days deducted
• If you have used Bonus Days on a given project, I will send you an email (well, a Python script will, actually) telling you how many you used and how many you have left.

A Warning About Virtual Machines

Virtual machines are, apparently, not automatically setup to do multithreading.

If you are running on your own virtual machine, and are getting performance numbers that make absolutely no sense, try using one of the OSU machines.
A Warning about Editing on Windows and Running on Linux

Some of you will end up having strange, unexplainable problems with your csh scripts or .cpp programs. This could be because you are typing your code in on Windows (using Notepad or Wordpad or Word) and then running it on Linux. Windows likes to insert an extra carriage return ('\r') at the end of each line, which Linux interprets as a garbage character.

You can confirm this by typing the Linux command:

```
od -c loop.csh
```

which will show you all the characters, even the '\r' (carriage returns, which you don't want) and the '\n' (newlines, which you do want).

To get rid of the carriage returns, enter the Linux command:

```
tr -d '\r' < loop.csh > loop1.csh
```

Then run loop1.csh

This works too:

```
sed -i -e 's/\r$/\n' loop.csh
```

Or, on some systems, there is a utility called dos2unix which does this for you:

```
dos2unix < loop.csh > loop1.csh
```

Sorry about this. Unfortunately, this is a fact of life when you mix Windows and Linux.
