# Chapter 2 Application Layer

# Chapter 2: Application layer

- 2.1 Principles of network applications
- □ 2.2 Web and HTTP
- 2.3 Electronic Mail
   SMTP, POP3, IMAP
- 2.4 Socket
  - programming with TCP

### 2.5 Socket programming with UDP

2.6 DNS2.7 P2P file sharing

# Chapter 2: Application Layer

### <u>Our goals:</u>

- conceptual, implementation aspects of network application protocols
  - transport-layer service models
  - client-server paradigm
  - peer-to-peer
     paradigm

- learn about protocols by examining popular application-level protocols
  - o HTTP
  - FTP
  - SMTP / POP3 / IMAP
  - DNS
- programming network applications
  - socket API

## Some network apps

- 🗖 E-mail
- 🗖 Web
- Instant messaging
- Remote login
- P2P file sharing
- Multi-user network games
- Streaming stored video clips

- Internet telephone
- Real-time video conference
- Massive parallel computing

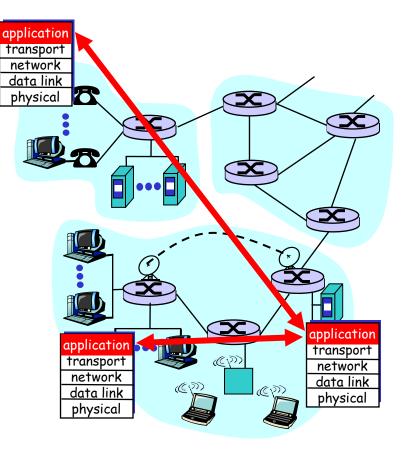

## Creating a network app

### Write programs that

- run on different end systems and
- communicate over a network.
- e.g., Web: Web server software communicates with browser software

# No software written for devices in network core

- Network core devices do not function at app layer
- This design allows for rapid app development

# Chapter 2: Application layer

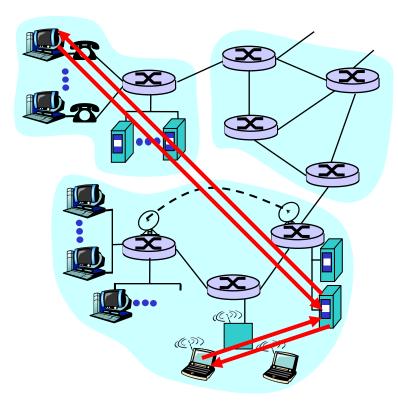

- 2.1 Principles of network applications
- 2.2 Web and HTTP
- **2.3 FTP**
- 2.4 Electronic Mail
   SMTP, POP3, IMAP
   2.5 DNS

- □ 2.6 P2P file sharing
- 2.7 Socket programming with TCP
- 2.8 Socket programming with UDP
- 2.9 Building a Web server

# **Application architectures**

Client-server
Peer-to-peer (P2P)
Hybrid of client-server and P2P

## <u>Client-server archicture</u>

#### server:

- o always-on host
- permanent IP address
- server farms for scaling

#### clients:

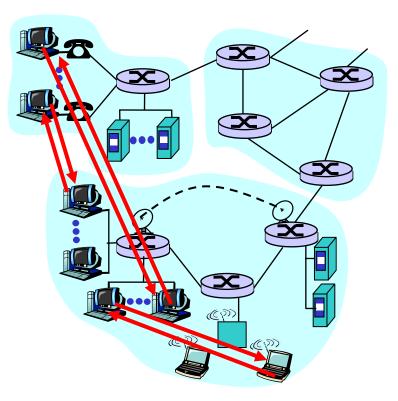

- communicate with server
- may be intermittently connected
- may have dynamic IP addresses
- do not communicate directly with each other

## Pure P2P architecture

- no always on server
- arbitrary end systems directly communicate
- peers are intermittently connected and change IP addresses
- 🗖 example: Gnutella

Highly scalable

But difficult to manage

# Hybrid of client-server and P2P

### Napster

- File transfer P2P
- File search centralized:
  - Peers register content at central server
  - Peers query same central server to locate content

### Instant messaging

- Chatting between two users is P2P
- Presence detection/location centralized:
  - User registers its IP address with central server when it comes online
  - User contacts central server to find IP addresses of buddies

## Processes communicating

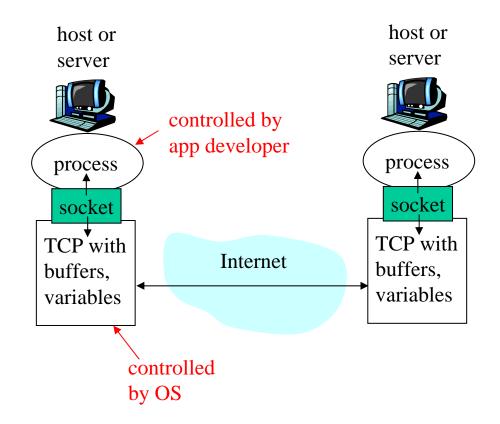

- Process: program running within a host.
- within same host, two processes communicate using inter-process communication (defined by OS).
- processes in different hosts communicate by exchanging messages

Client process: process that initiates communication Server process: process that waits to be contacted

Note: applications with P2P architectures have client processes & server processes

## <u>Sockets</u>

- process sends/receives messages to/from its socket
- socket analogous to door
  - sending process shoves message out door
  - sending process relies on transport infrastructure on other side of door which brings message to socket at receiving process

API: (1) choice of transport protocol; (2) ability to fix a few parameters (lots more on this later)

### Addressing processes

- For a process to receive messages, it must have an identifier
- A host has a unique32bit IP address
- Q: does the IP address of the host on which the process runs suffice for identifying the process?
- Answer: No, many processes can be running on same host

- Identifier includes both the IP address and port numbers associated with the process on the host.
- Example port numbers:
  HTTP server: 80
  Mail server: 25
- □ More on this later

## App-layer protocol defines

- Types of messages exchanged, eg, request & response messages
- Syntax of message types: what fields in messages & how fields are delineated
- Semantics of the fields, ie, meaning of information in fields
- Rules for when and how processes send & respond to messages

### Public-domain protocols:

- defined in RFCs
- allows for interoperability
- □ eg, HTTP, SMTP

### Proprietary protocols:

🗖 eg, KaZaA

### What transport service does an app need?

#### Data loss

- some apps (e.g., audio) can tolerate some loss
- other apps (e.g., file transfer, telnet) require 100% reliable data transfer

### Timing

some apps (e.g., Internet telephony, interactive games) require low delay to be "effective"

### Bandwidth

- some apps (e.g., multimedia) require minimum amount of bandwidth to be "effective"
- other apps ("elastic apps") make use of whatever bandwidth they get

### Transport service requirements of common apps

|                | Application    | Data loss     | Bandwidth          | Time Sensitive  |
|----------------|----------------|---------------|--------------------|-----------------|
|                | file transfer  | no loss       | elastic            | no              |
| -              | e-mail         | no loss       | elastic            | no              |
| $\overline{V}$ | Veb documents  | no loss       | elastic            | no              |
| real-ti        | me audio/video | loss-tolerant | audio: 5kbps-1Mbps | yes, 100's msec |
| _              |                |               | video:10kbps-5Mbps |                 |
|                | ed audio/video | loss-tolerant | same as above      | yes, few secs   |
| inte           | eractive games | loss-tolerant | few kbps up        | yes, 100's msec |
| inst           | ant messaging  | no loss       | elastic            | yes and no      |

### Internet transport protocols services

### TCP service:

- connection-oriented: setup required between client and server processes
- reliable transport between sending and receiving process
- flow control: sender won't overwhelm receiver
- congestion control: throttle sender when network overloaded
- does not provide: timing, minimum bandwidth guarantees

#### <u>UDP service:</u>

- unreliable data transfer between sending and receiving process
- does not provide: connection setup, reliability, flow control, congestion control, timing, or bandwidth guarantee
- Q: why bother? Why is there a UDP?

### Internet apps: application, transport protocols

| Application            | Application<br>layer protocol | Underlying<br>transport protocol |
|------------------------|-------------------------------|----------------------------------|
|                        |                               |                                  |
| e-mail                 | SMTP [RFC 2821]               | TCP                              |
| remote terminal access | Telnet [RFC 854]              | TCP                              |
| Web                    | HTTP [RFC 2616]               | TCP                              |
| file transfer          | FTP [RFC 959]                 | TCP                              |
| streaming multimedia   | proprietary                   | TCP or UDP                       |
|                        | (e.g. RealNetworks)           |                                  |
| Internet telephony     | proprietary                   |                                  |
|                        | (e.g., Dialpad)               | typically UDP                    |

### www.ietf.org

#### Internet engineering task force

# Chapter 2: Application layer

- 2.1 Principles of network applications

   app architectures
   app requirements
- □ 2.2 Web and HTTP
- 2.3 Electronic Mail
   SMTP, POP3, IMAP

- 2.4 Socket programming with TCP
- 2.5 Socket programming with UDP
- **2.6 DNS**
- □ 2.7 P2P file sharing

# Web and HTTP

### First some jargon

Web page consists of objects

- Object can be HTML file, JPEG image, Java applet, audio file,...
- Web page consists of base HTML-file which includes several referenced objects
- Each object is addressable by a URL
- Example URL:

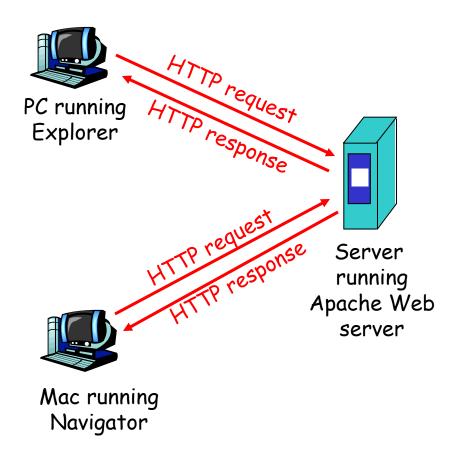

```
www.someschool.edu/someDept/pic.gif
```

host name

path name

## HTTP overview

- HTTP: hypertext transfer protocol
- Web's application layer protocol
- client/server model
  - *client:* browser that requests, receives, "displays" Web objects
- *server:* Web server sends objects in response to requests
   HTTP 1.0: RFC 1945
   HTTP 1.1: RFC 2068

# HTTP overview (continued)

#### Uses TCP:

- client initiates TCP connection (creates socket) to server, port 80
- server accepts TCP connection from client
- HTTP messages (applicationlayer protocol messages) exchanged between browser (HTTP client) and Web server (HTTP server)
- TCP connection closed

### HTTP is "stateless"

- server maintains no information about past client requests
- Protocols that maintain "state" are complex!
- past history (state) must be maintained
- if server/client crashes, their views of "state" may be inconsistent, must be reconciled

# HTTP connections

### Nonpersistent HTTP

- At most one object is sent over a TCP connection.
- HTTP/1.0 uses nonpersistent HTTP

### Persistent HTTP

- Multiple objects can be sent over single TCP connection between client and server.
- HTTP/1.1 uses persistent connections in default mode

## Nonpersistent HTTP

time

(contains text, Suppose user enters URL references to 10 www.someSchool.edu/someDepartment/home.index jpeg images) 1a. HTTP client initiates TCP connection to HTTP server 1b. HTTP server at host (process) at www.someSchool.edu waiting www.someSchool.edu on port 80 for TCP connection at port 80. "accepts" connection, notifying client 2 HTTP client sends HTTP request message (containing URL) into TCP connection . 3. HTTP server receives request socket. Message indicates message, forms response that client wants object message containing requested object, and sends message someDepartment/home.index into its socket

## Nonpersistent HTTP (cont.)

5. HTTP client receives response message containing html file, displays html. Parsing html file, finds 10 referenced jpeg objects

6. Steps 1-5 repeated for each of 10 jpeg objects

time

4. HTTP server closes TCP connection.

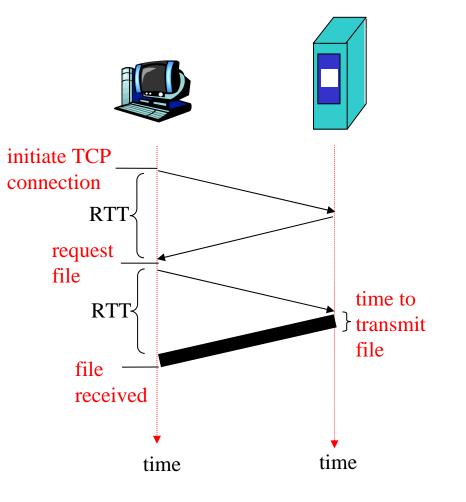

# Response time modeling

Definition of RTT: time to send a small packet to travel from client to server and back.

<u>Response time:</u>

- one RTT to initiate TCP connection
- one RTT for HTTP request and first few bytes of HTTP response to return
- file transmission time

total = 2RTT+transmit time

### Persistent HTTP

#### Nonpersistent HTTP issues:

- requires 2 RTTs per object
- OS must work and allocate host resources for each TCP connection
- but browsers often open parallel TCP connections to fetch referenced objects

#### Persistent HTTP

- server leaves connection
   open after sending response
- subsequent HTTP messages between same client/server are sent over connection

#### Persistent without pipelining:

- client issues new request only when previous response has been received
- one RTT for each referenced object

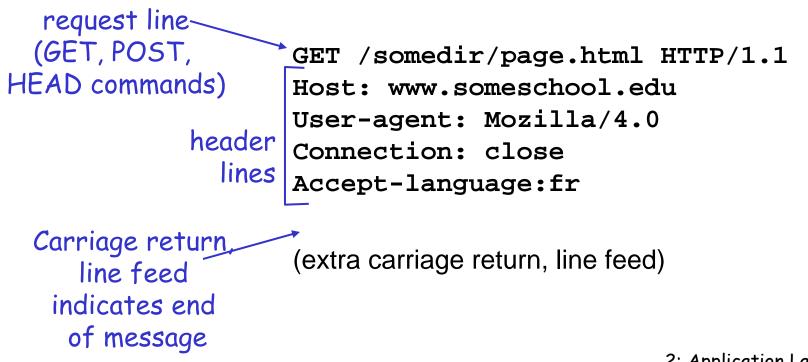

#### Persistent with pipelining:

- default in HTTP/1.1
- client sends requests as soon as it encounters a referenced object
- as little as one RTT for all the referenced objects

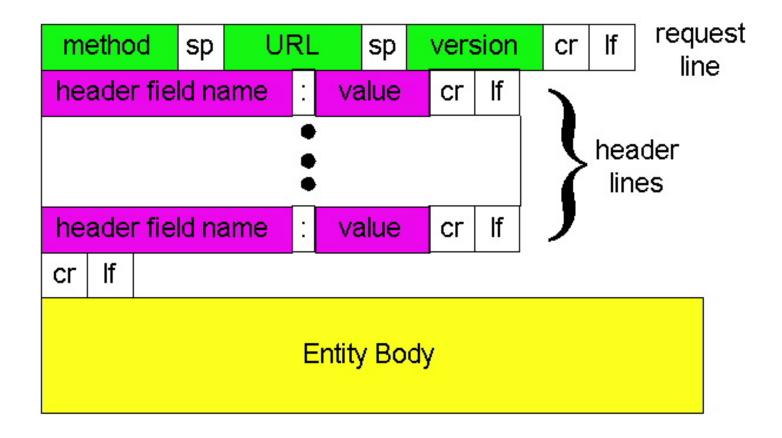

### <u>HTTP request message</u>

two types of HTTP messages: *request, response* HTTP request message:

• ASCII (human-readable format)

### HTTP request message: general format

# **Uploading form input**

### Post method:

- Web page often includes form input
- Input is uploaded to server in entity body

### URL method:

- Uses GET method
- Input is uploaded in URL field of request line:

www.somesite.com/animalsearch?monkeys&banana

# Method types

<u>HTTP/1.0</u>

- 🗆 GET
- D POST
- HEAD
  - asks server to leave requested object out of response

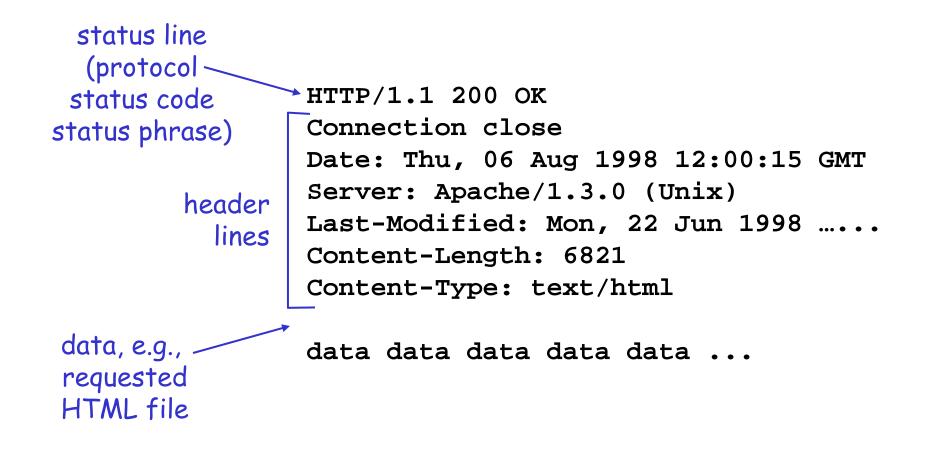

### <u>HTTP/1.1</u>

GET, POST, HEAD

### 

- uploads file in entity body to path specified in URL field
- DELETE
  - deletes file specified in the URL field

### HTTP response message

### HTTP response status codes

In first line in server->client response message. A few sample codes:

200 ОК

• request succeeded, requested object later in this message

#### 301 Moved Permanently

- requested object moved, new location specified later in this message (Location:)
- 400 Bad Request
  - request message not understood by server
- 404 Not Found
  - requested document not found on this server
- 505 HTTP Version Not Supported

### Trying out HTTP (client side) for yourself

### 1. Telnet to your favorite Web server:

telnet web.engr.orst.edu Opens TCP connection to port 80 (default HTTP server port) at web.engr.orst.edu. Anything typed in sent to port 80 at cis.poly.edu

2. Type in a GET HTTP request:

GET /~thinhq/index.html HTTP/1.1 Host: kingsalmon.eecs.orst.edu

By typing this in (hit carriage return twice), you send this minimal (but complete) GET request to HTTP server

3. Look at response message sent by HTTP server!

### <u>User-server state: cookies</u>

Many major Web sites use cookies

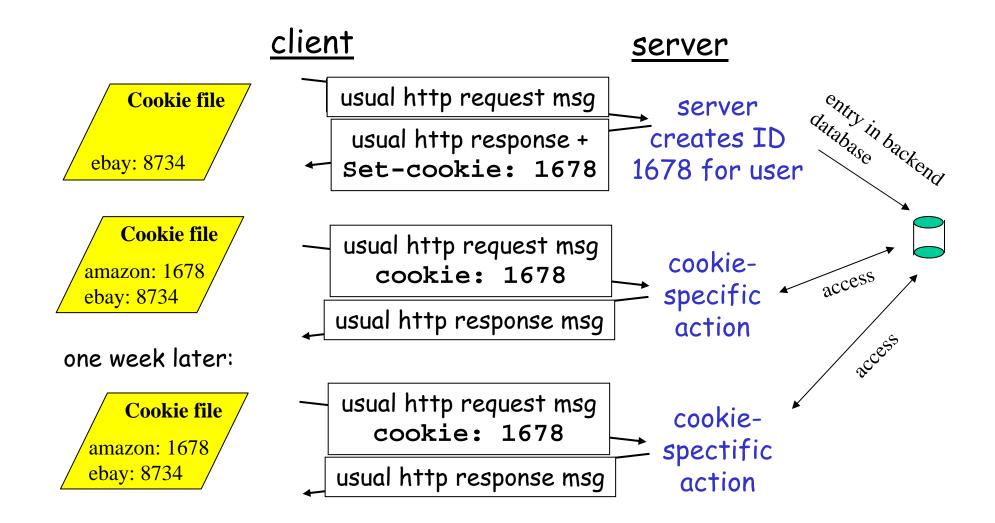

#### Four components:

- 1) cookie header line in the HTTP response message
- 2) cookie header line in HTTP request message
- cookie file kept on user's host and managed by user's browser
- 4) back-end database at Web site

### Example:

- Susan access Internet always from same PC
- She visits a specific ecommerce site for first time
- When initial HTTP requests arrives at site, site creates a unique ID and creates an entry in backend database for ID

### Cookies: keeping "state" (cont.)

# Cookies (continued)

### What cookies can bring:

- authorization
- shopping carts
- recommendations
- user session state (Web e-mail)

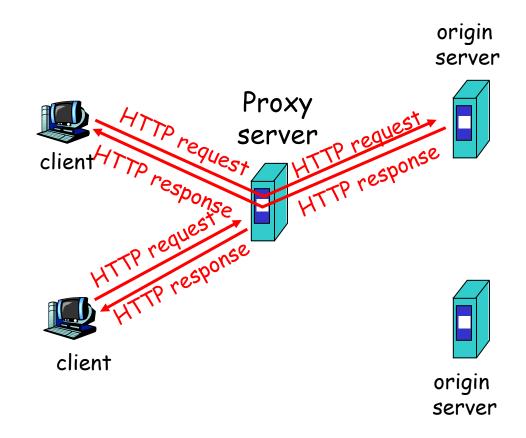

## <u>Cookies and privacy:</u>

- cookies permit sites to learn a lot about you
- you may supply name and e-mail to sites
- search engines use redirection & cookies to learn yet more
- advertising companies obtain info across sites

## Web caches (proxy server)

Goal: satisfy client request without involving origin server

- user sets browser: Web accesses via cache
- browser sends all HTTP requests to cache
  - object in cache: cache returns object
  - else cache requests object from origin server, then returns object to client

## More about Web caching

- Cache acts as both client and server
- Typically cache is installed by ISP (university, company, residential ISP)

### Why Web caching?

- Reduce response time for client request.
- Reduce traffic on an institution's access link.
- Internet dense with caches enables "poor" content providers to effectively deliver content (but so does P2P file sharing)

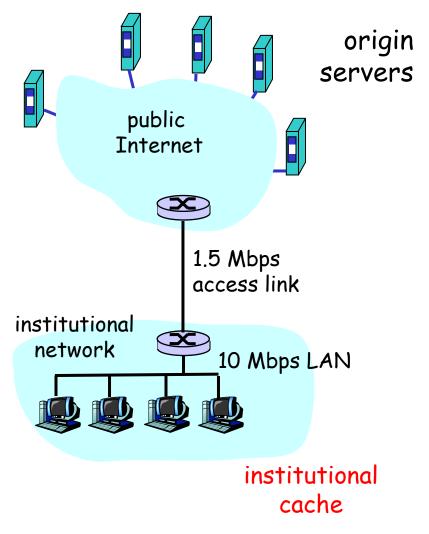

## Caching example

#### **Assumptions**

- average object size = 100,000 bits
- avg. request rate from institution's browsers to origin servers = 15/sec
- delay from institutional router to any origin server and back to router = 2 sec

#### <u>Consequences</u>

- utilization on LAN = 15%
- utilization on access link = 100%
- total delay = Internet delay + access delay + LAN delay
  - = 2 sec + minutes + milliseconds

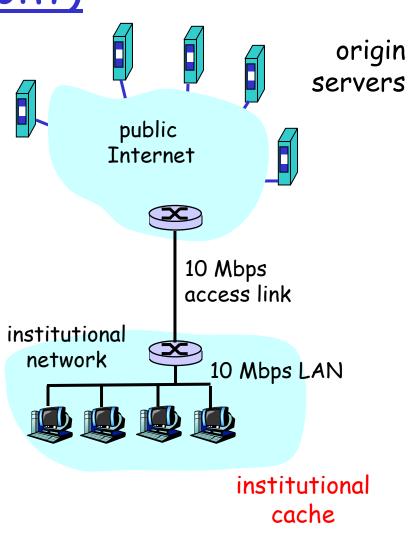

## Caching example (cont)

#### Possible solution

increase bandwidth of access link to, say, 10 Mbps

#### <u>Consequences</u>

- utilization on LAN = 15%
- utilization on access link = 15%
- Total delay = Internet delay + access delay + LAN delay
  - = 2 sec + msecs + msecs
- often a costly upgrade

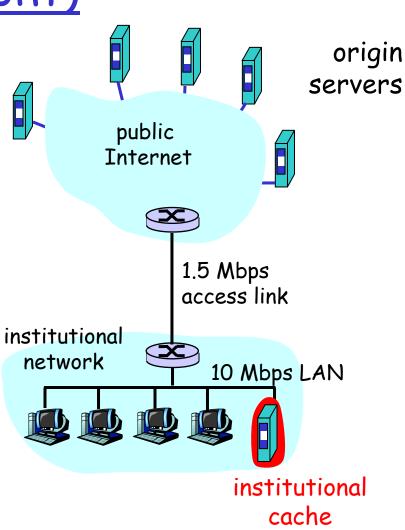

## Caching example (cont)

### Install cache

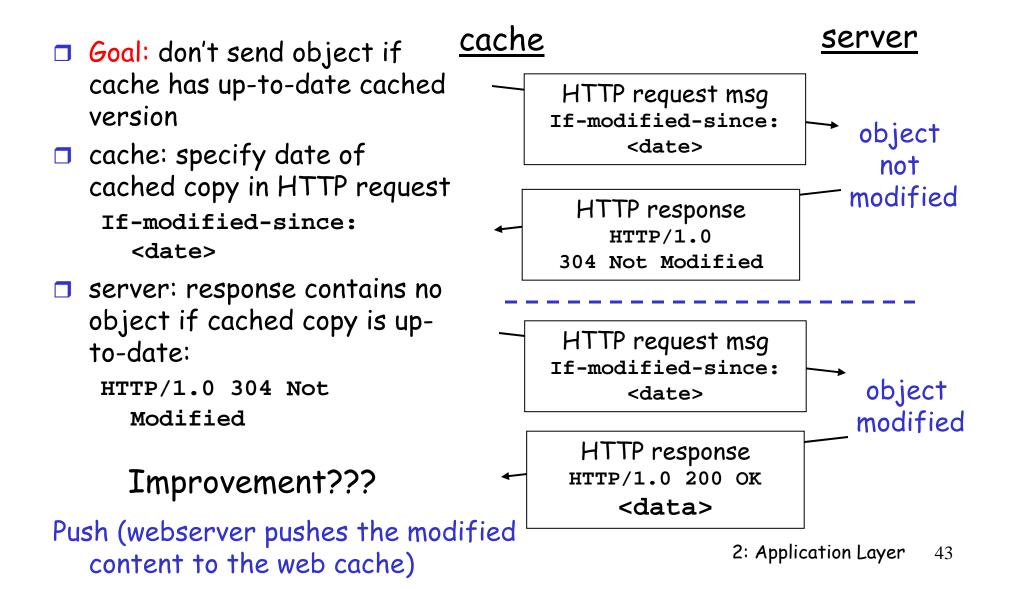

suppose hit rate is .4

#### Consequence

- 40% requests will be satisfied almost immediately
- 60% requests satisfied by origin server
- utilization of access link reduced to 60%, resulting in negligible delays (say 10 msec)
- total avg delay = Internet delay + access delay + LAN delay = .6\*(2.01) secs .4\*(.01) secs < 1.4 secs</p>

### Conditional GET

# Chapter 2: Application layer

- 2.1 Principles of network applications
- □ 2.2 Web and HTTP
- 2.3 Electronic Mail
  - SMTP, POP3, IMAP
- 2.4 Socket
  - programming with TCP

### 2.5 Socket programming with UDP

2.6 DNS2.7 P2P file sharing

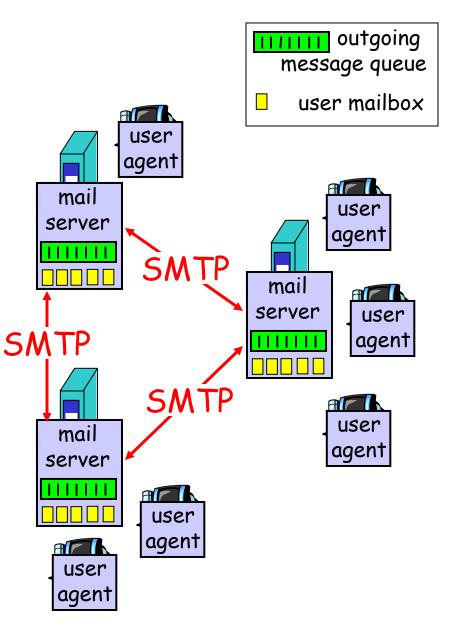

## Electronic Mail

### Three major components:

- user agents
- mail servers
- simple mail transfer protocol: SMTP

#### <u>User Agent</u>

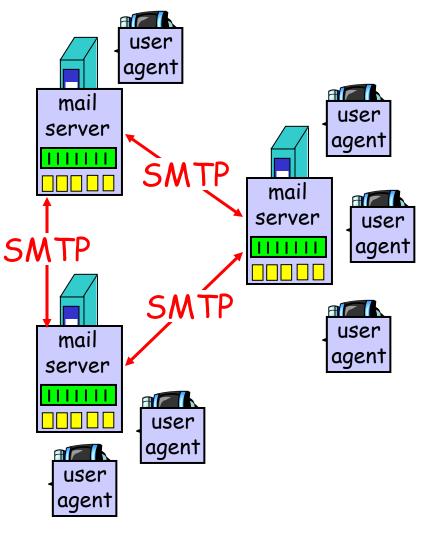

- a.k.a. "mail reader"
- composing, editing, reading mail messages
- e.g., Eudora, Outlook, elm, Netscape Messenger
- outgoing, incoming messages stored on server

## Electronic Mail: mail servers

### Mail Servers

- mailbox contains incoming messages for user
- message queue of outgoing (to be sent) mail messages
- SMTP protocol between mail servers to send email messages
  - client: sending mail server
  - "server": receiving mail server

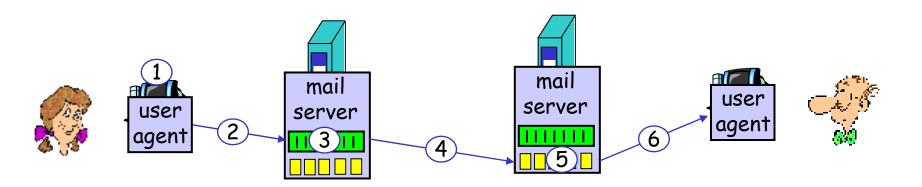

### Electronic Mail: SMTP [RFC 2821]

- uses TCP to reliably transfer email message from client to server, port 25
- direct transfer: sending server to receiving server
- three phases of transfer
  - o handshaking (greeting)
  - transfer of messages
  - o closure
- command/response interaction
  - o commands: ASCII text
  - response: status code and phrase
- messages must be in 7-bit ASCII

### Scenario: Alice sends message to Bob

- 1) Alice uses UA to compose message and "to" bob@someschool.edu
- 2) Alice's UA sends message to her mail server; message placed in message queue
- 3) Client side of SMTP opens TCP connection with Bob's mail server

- 4) SMTP client sends Alice's message over the TCP connection
- 5) Bob's mail server places the message in Bob's mailbox
- 6) Bob invokes his user agent to read message

### Sample SMTP interaction

- S: 220 hamburger.edu
- C: HELO crepes.fr
- S: 250 Hello crepes.fr, pleased to meet you
- C: MAIL FROM: <alice@crepes.fr>
- S: 250 alice@crepes.fr... Sender ok
- C: RCPT TO: <bob@hamburger.edu>
- S: 250 bob@hamburger.edu ... Recipient ok
- C: DATA
- S: 354 Enter mail, end with "." on a line by itself
- C: Do you like ketchup?
- C: How about pickles?
- C: .
- S: 250 Message accepted for delivery
- C: QUIT
- S: 221 hamburger.edu closing connection

### Try SMTP interaction for yourself:

□ telnet servername 25

• telnet mail.ece.orst.edu 25

- □ see 220 reply from server
- enter HELO, MAIL FROM, RCPT TO, DATA, QUIT commands

above lets you send email without using email client (reader)

# SMTP: final words

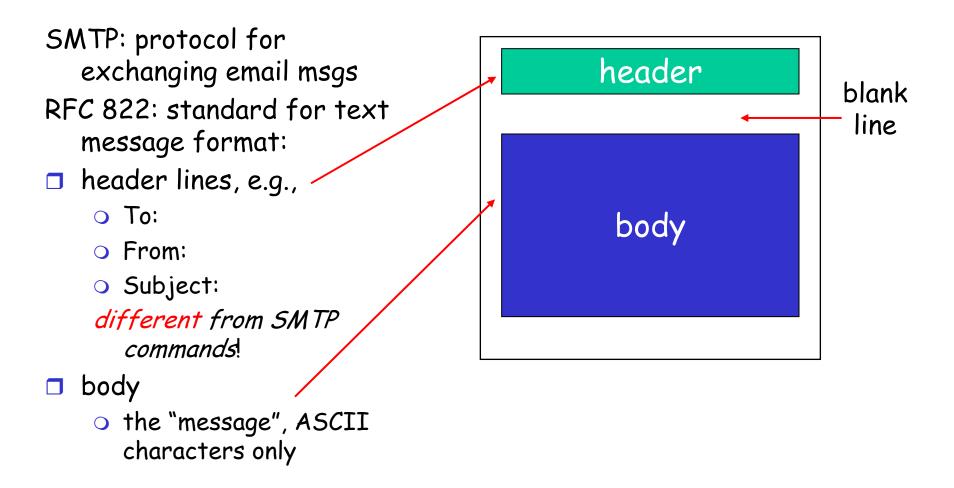

- SMTP uses persistent connections
- SMTP requires message (header & body) to be in 7bit ASCII
- SMTP server uses
   CRLF.CRLF to determine
   end of message

### Comparison with HTTP:

- HTTP: pull
- □ SMTP: push
- both have ASCII command/response interaction, status codes
- HTTP: each object encapsulated in its own response msg
- SMTP: multiple objects sent in multipart msg

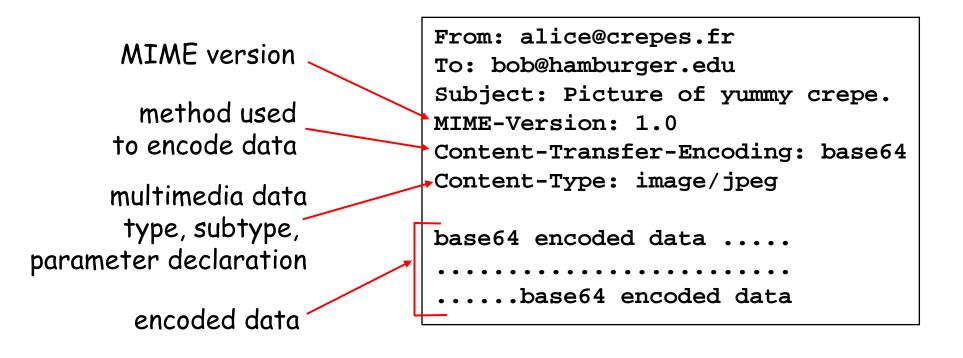

# Mail message format (not covered in

lecture - read by yourself)

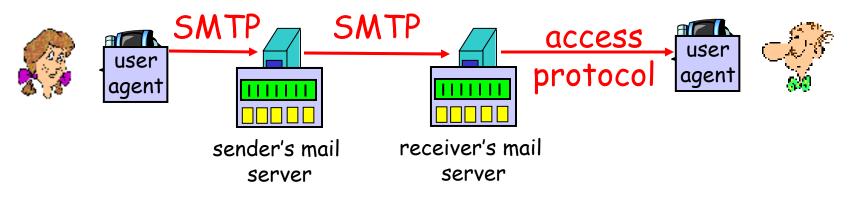

### Message format: multimedia extensions

- □ MIME: multimedia mail extension, RFC 2045, 2056
- additional lines in msg header declare MIME content type

# Mail access protocols

- □ SMTP: delivery/storage to receiver's server
- Mail access protocol: retrieval from server
  - POP: Post Office Protocol [RFC 1939]
    - authorization (agent <-->server) and download
  - IMAP: Internet Mail Access Protocol [RFC 1730]
    - more features (more complex)
    - manipulation of stored msgs on server
  - HTTP: Hotmail , Yahoo! Mail, etc.

| POP3 protocol (not covered in lecture - read by |   |
|---|---|
| yourself)                                       | S: +OK POP3 server ready                |
|   | C: user bob                             |
| authorization phase                             | S: +OK                                  |
| client commands:                                | C: pass hungry                          |
|   | S: +OK user successfully logged on      |
| user: declare username                          | C: list                                 |
| o pass: password                                | S: 1 498                                |
| server responses                                | S: 2 912                                |
| O +OK   | S: .                                    |
|   | C: retr 1                               |
| ○ −ERR  | S: <message 1="" contents=""></message> |
| transaction phase, client:                      | S: .                                    |
|   | C: dele 1                               |
| list: list message numbers                      | C: retr 2                               |
| retr: retrieve message by                       | S: <message 1="" contents=""></message> |
| number  | S: .                                    |
| 🗖 dele: delete                                  | C: dele 2                               |
|   | C: quit                                 |
| 🗖 quit  | S: +OK POP3 server signing off          |
|   |   |

#### 2: Application Layer 55

# POP3 (more) and IMAP (not covered in

lecture - read by yourself)

### More about POP3

- Previous example uses "download and delete" mode.
- Bob cannot re-read email if he changes client
- Download-and-keep": copies of messages on different clients
- POP3 is stateless across sessions

### IMAP

- Keep all messages in one place: the server
- Allows user to organize messages in folders
- IMAP keeps user state across sessions:
  - names of folders and mappings between message IDs and folder name

# Chapter 2: Application layer

- 2.1 Principles of network applications
- 2.2 Web and HTTP
- 2.3 Electronic Mail
   SMTP, POP3, IMAP
- 2.4 Socket

programming with TCP

2.5 Socket

programming with UDP

2.6 DNS2.7 P2P file sharing

# Socket programming

<u>Goal:</u> learn how to build client/server application that communicate using sockets

### Socket API

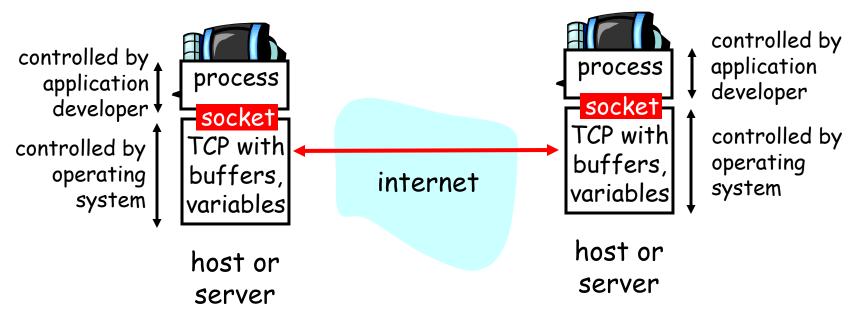

- introduced in BSD4.1 UNIX, 1981
- explicitly created, used, released by apps
- client/server paradigm
- two types of transport service via socket API:
  - unreliable datagram
  - reliable, byte streamoriented

### r socket

a *host-local*, *application-created*, *OS-controlled* interface (a "door") into which application process can both send and receive messages to/from another application process

## Socket-programming using TCP

<u>Socket:</u> a door between application process and endend-transport protocol (UCP or TCP) <u>TCP service:</u> reliable transfer of bytes from one process to another

## Socket programming with TCP

#### Client must contact server

- server process must first be running
- server must have created socket (door) that welcomes client's contact

#### Client contacts server by:

- creating client-local TCP socket
- specifying IP address, port number of server process
- When client creates socket: client TCP establishes connection to server TCP

- When contacted by client, server TCP creates new socket for server process to communicate with client
  - allows server to talk with multiple clients
  - source port numbers used to distinguish clients (more in Chap 3)

#### -application viewpoint-

TCP provides reliable, in-order transfer of bytes ("pipe") between client and server

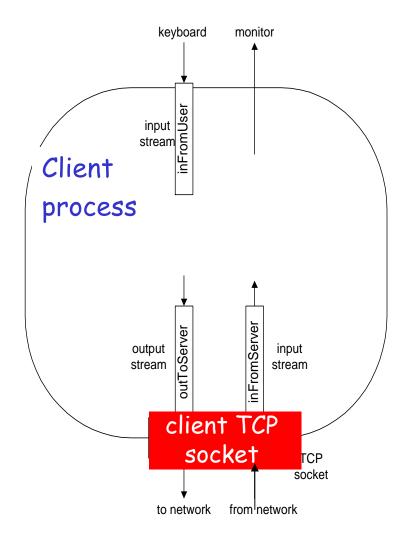

## Stream jargon

- A stream is a sequence of characters that flow into or out of a process.
- An input stream is attached to some input source for the process, eg, keyboard or socket.
- An output stream is attached to an output source, eg, monitor or socket.

## Socket programming with TCP

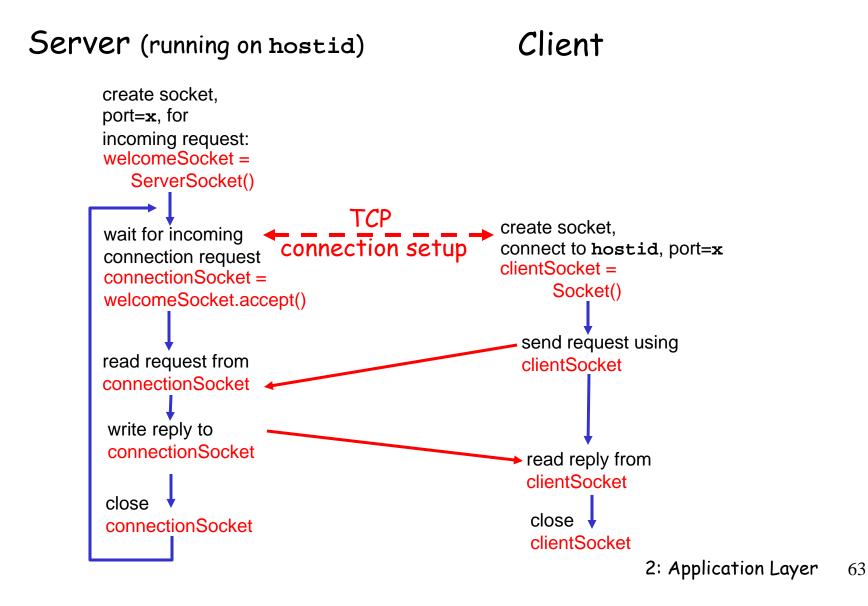

### Example client-server app:

- client reads line from standard input (inFromUser stream), sends to server via socket (outToServer stream)
- 2) server reads line from socket
- 3) server converts line to uppercase, sends back to client
- 4) client reads, prints modified line from socket (inFromServer stream)

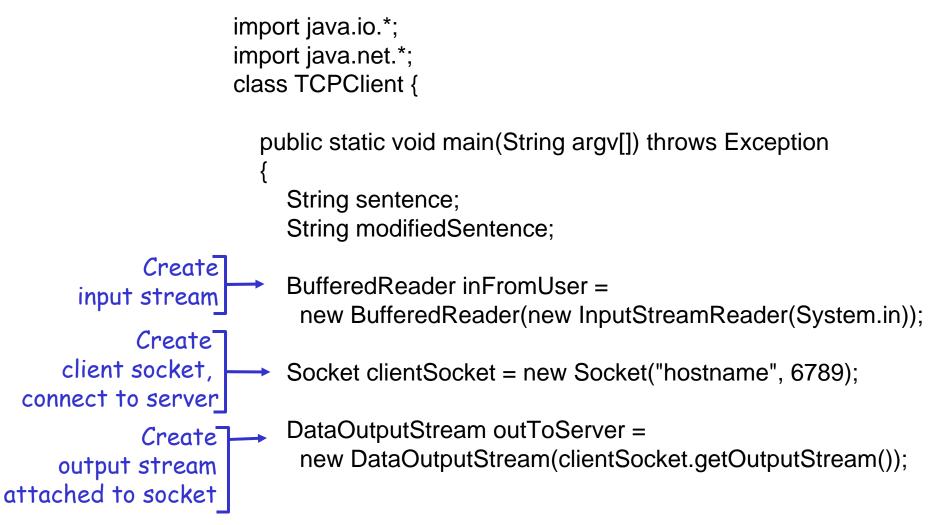

2: Application Layer 62

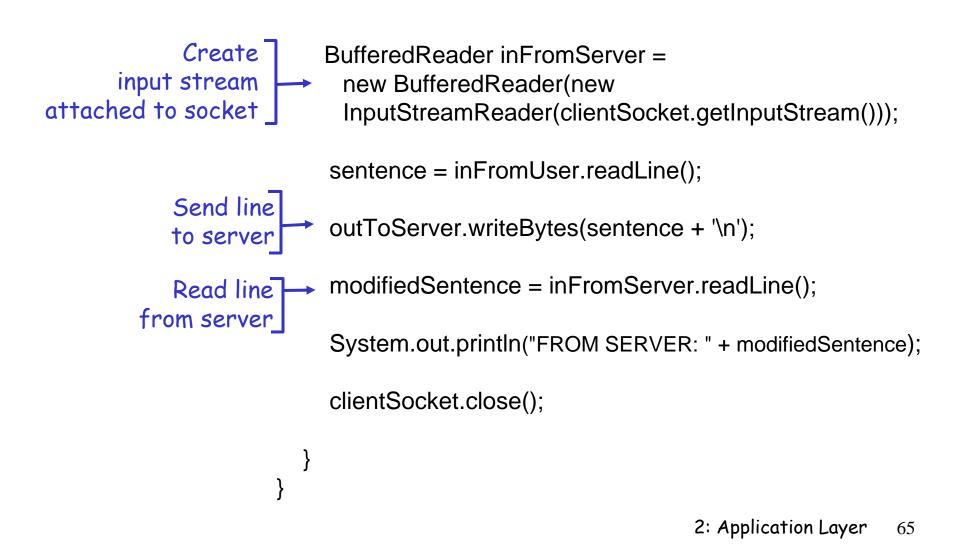

### <u>Client/server socket interaction: TCP</u>

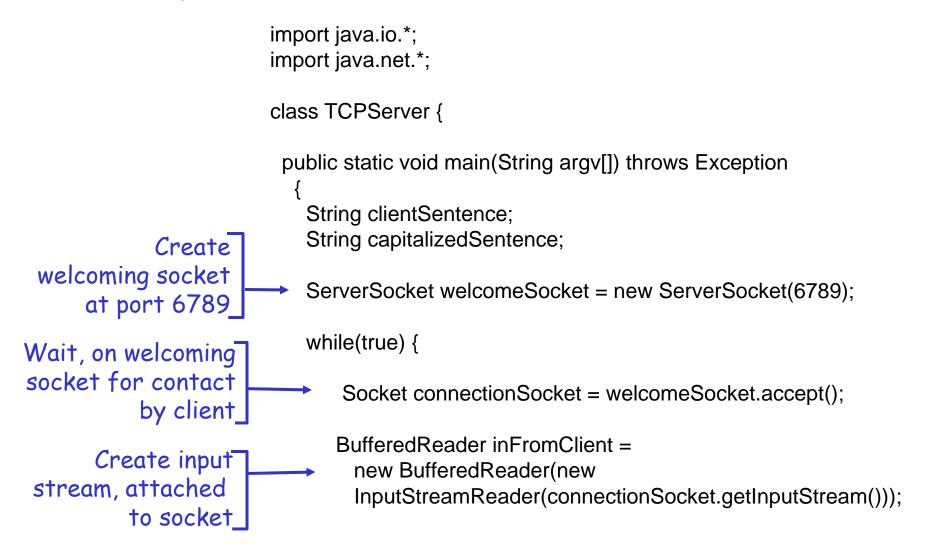

## Example: Java client (TCP)

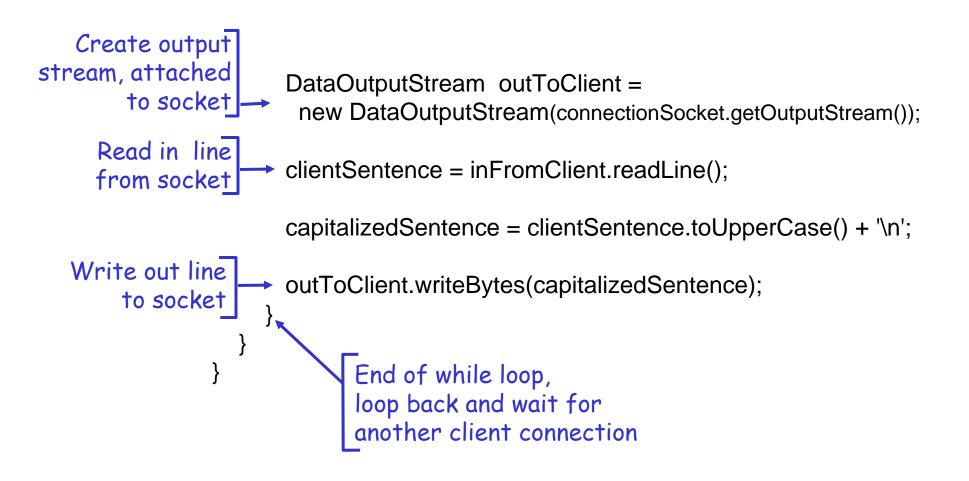

## Example: Java client (TCP), cont.

### Example: Java server (TCP)

## Example: Java server (TCP), cont

# Chapter 2: Application layer

- 2.1 Principles of network applications
- □ 2.2 Web and HTTP
- 2.3 Electronic Mail
   SMTP, POP3, IMAP
- 2.4 Socket
  - programming with TCP
- □ 2.6 Socket
  - programming with UDP

2.7 DNS2.8 P2P file sharing

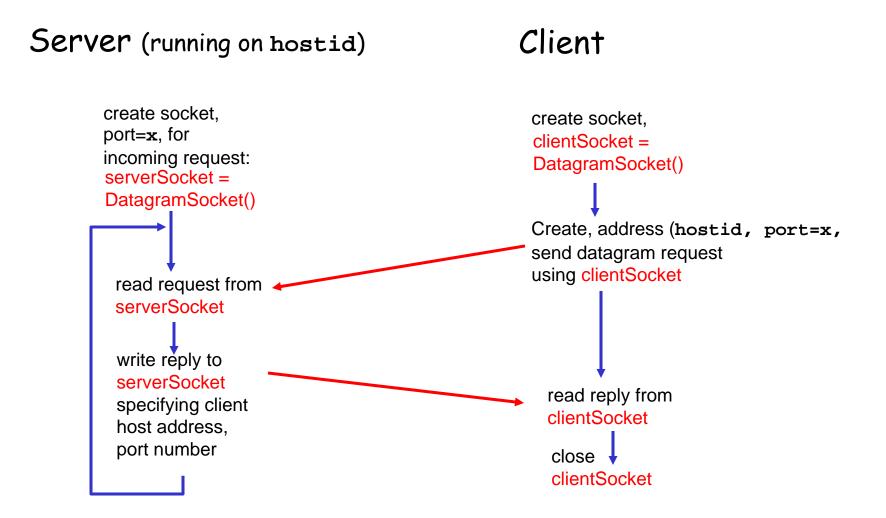

## Socket programming with UDP

- UDP: no "connection" between client and server
- no handshaking
- sender explicitly attaches
   IP address and port of
   destination to each packet
- server must extract IP address, port of sender from received packet
- UDP: transmitted data may be received out of order, or lost

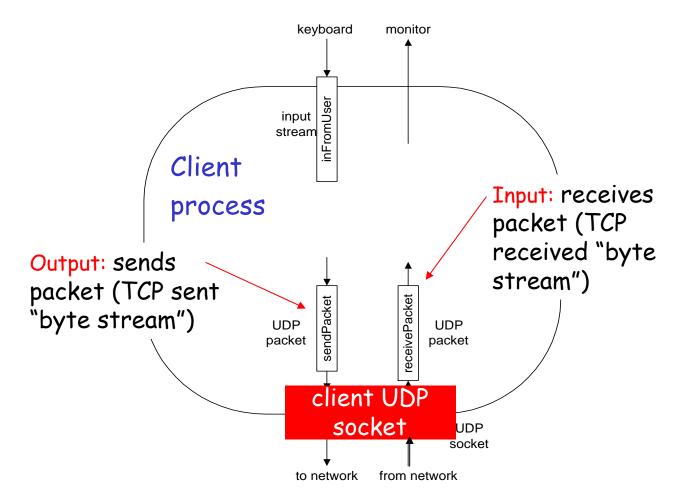

application viewpoint

UDP provides <u>unreliable</u> transfer of groups of bytes ("datagrams") between client and server

### <u>Client/server socket interaction: UDP</u>

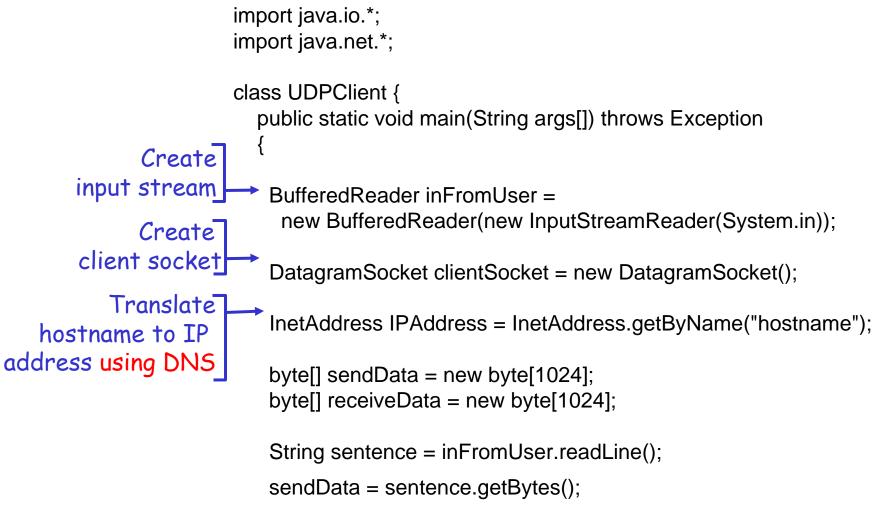

## Example: Java client (UDP)

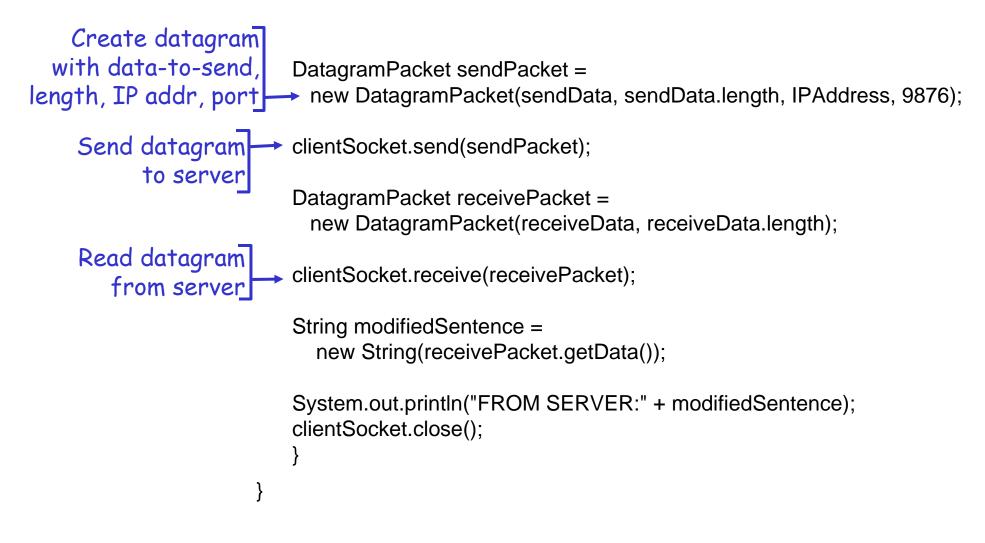

2: Application Layer 71

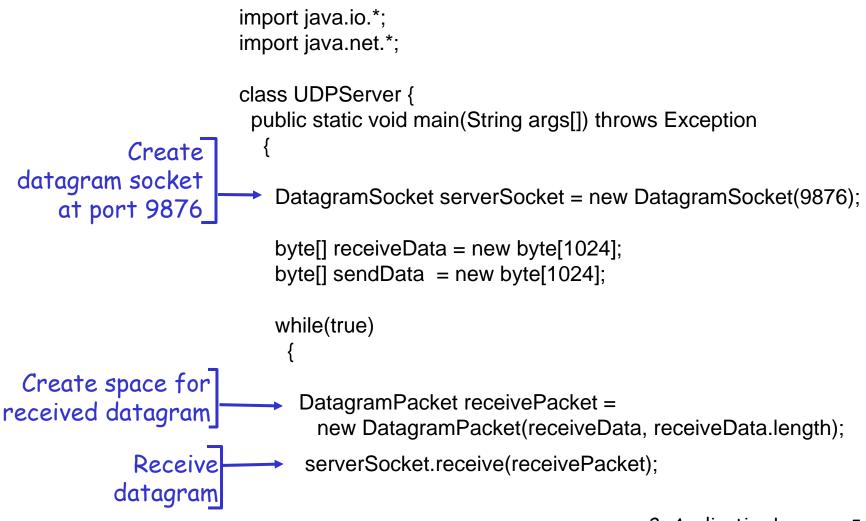

## Example: Java client (UDP)

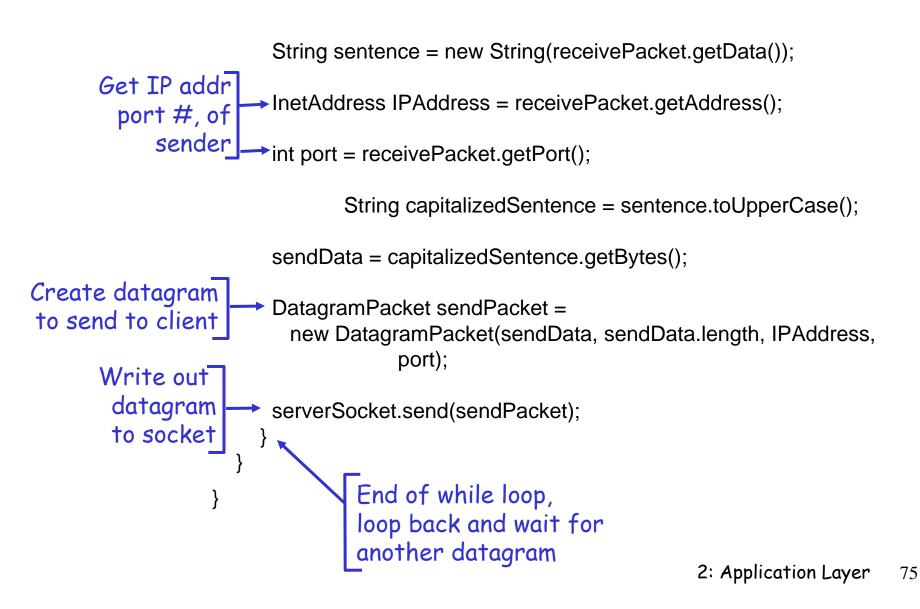

## Example: Java client (UDP), cont.

## Example: Java server (UDP)

## Example: Java server (UDP), cont

# Chapter 2: Application layer

- 2.1 Principles of network applications
- 2.2 Web and HTTP
- 2.3 Electronic Mail
   SMTP, POP3, IMAP
- 2.4 Socket
  - programming with TCP

## 2.5 Socket programming with UDP

2.6 DNS
2.7 P2P file sharing

## **DNS: Domain Name System**

## People: many identifiers:

SSN, name, passport #

## Internet hosts, routers:

- IP address (32 bit) used for addressing datagrams
- "name", e.g.,
   ww.yahoo.com used by
   humans
- Q: map between IP addresses and name ?

## Domain Name System:

- distributed database implemented in hierarchy of many name servers
- application-layer protocol host, routers, name servers to communicate to resolve names (address/name translation)
  - note: core Internet function, implemented as application-layer protocol
  - complexity at network's "edge"

## <u>DNS</u>

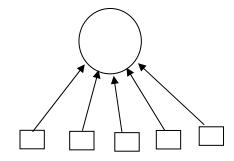

## **DNS** services

- Hostname to IP address translation
- Host aliasing
  - Canonical and alias names
- Mail server aliasing
- Load distribution
  - Replicated Web servers: set of IP addresses for one canonical name

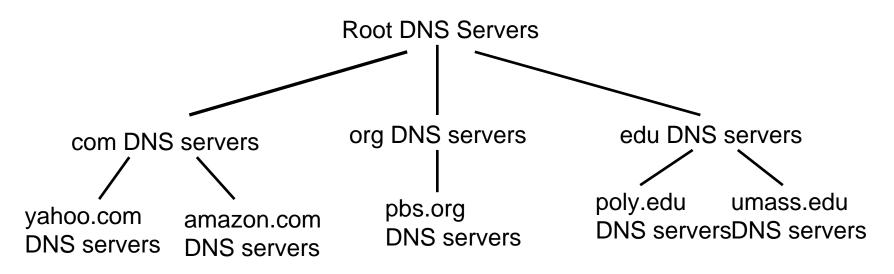

## Why not centralize DNS?

- □ single point of failure
- traffic volume
- distant centralized database
- maintenance

doesn't scale!

## Distributed, Hierarchical Database

<u>Client wants IP for www.amazon.com; 1st approx:</u>

- Client queries a root server to find com DNS server
- Client queries com DNS server to get amazon.com DNS server
- Client queries amazon.com DNS server to get IP address for www.amazon.com

## DNS: Root name servers

- contacted by local name server that can not resolve name
- root name server:
  - contacts authoritative name server if name mapping not known
  - gets mapping
  - returns mapping to local name server

# TLD and Authoritative Servers

- Top-level domain (TLD) servers: responsible for com, org, net, edu, etc, and all top-level country domains uk, fr, ca, jp.
  - Network solutions maintains servers for com TLD
  - Educause for edu TLD
- Authoritative DNS servers: organization's DNS servers, providing authoritative hostname to IP mappings for organization's servers (e.g., Web and mail).
  - Can be maintained by organization or service provider

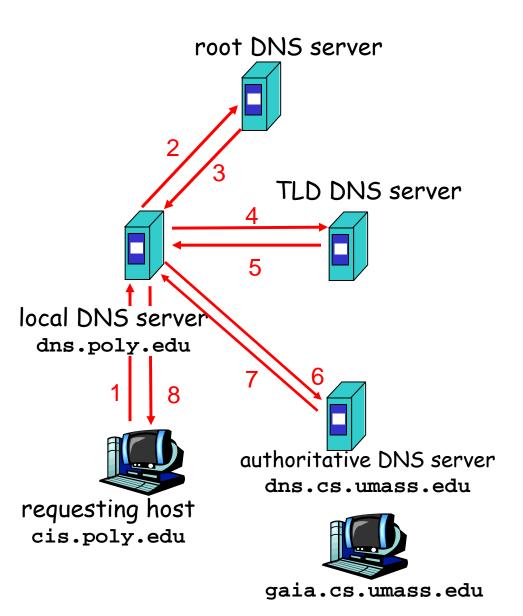

## Local Name Server

 Does not strictly belong to hierarchy
 Each ISP (residential ISP, company, university) has one.
 Also called "default name server"

- When a host makes a DNS query, query is sent to its local DNS server
  - Acts as a proxy, forwards query into hierarchy.

Host at cis.poly.edu wants IP address for gaia.cs.umass.edu

2: Application Layer 84

## DNS: caching and updating records

- once (any) name server learns mapping, it caches mapping
  - cache entries timeout (disappear) after some time
  - TLD servers typically cached in local name servers
    - Thus root name servers not often visited
- update/notify mechanisms under design by IETF
   RFC 2136
  - $\bigcirc$  RFC 2130
  - o http://www.ietf.org/html.charters/dnsind-charter.html

## DNS records

DNS: distributed db storing resource records (RR)

RR format: (name, value, type, ttl)

Type=A

- o name is hostname
- value is IP address
- Type=NS
  - name is domain (e.g. foo.com)
  - value is authoritative name server for this domain

□ Type=CNAME

- name is alias name for some "cannonical" (the real) name www.ibm.com is really servereast.backup2.ibm.com
- value is cannonical name

## Type=MX

 value is name of mailserver associated with name

## DNS protocol, messages

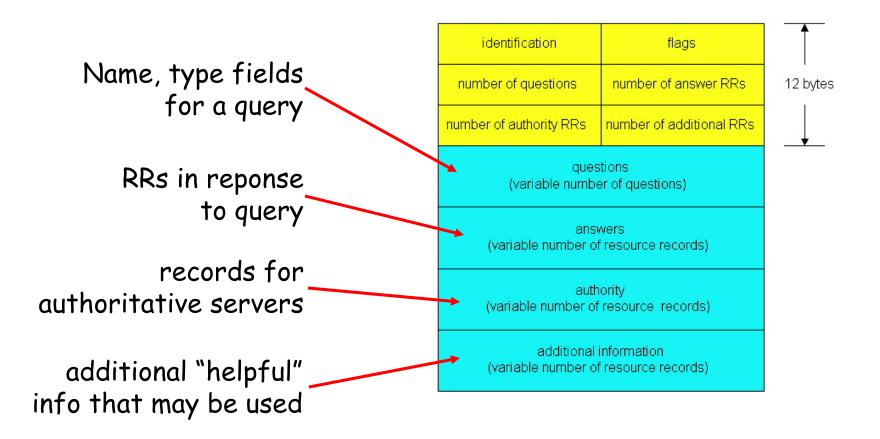

<u>DNS protocol</u> : *query* and *reply* messages, both with same *message format* 

### msg header

- identification: 16 bit # for query, reply to query uses same #
- □ flags:
  - query or reply
  - recursion desired
  - recursion available
  - reply is authoritative

## DNS protocol, messages

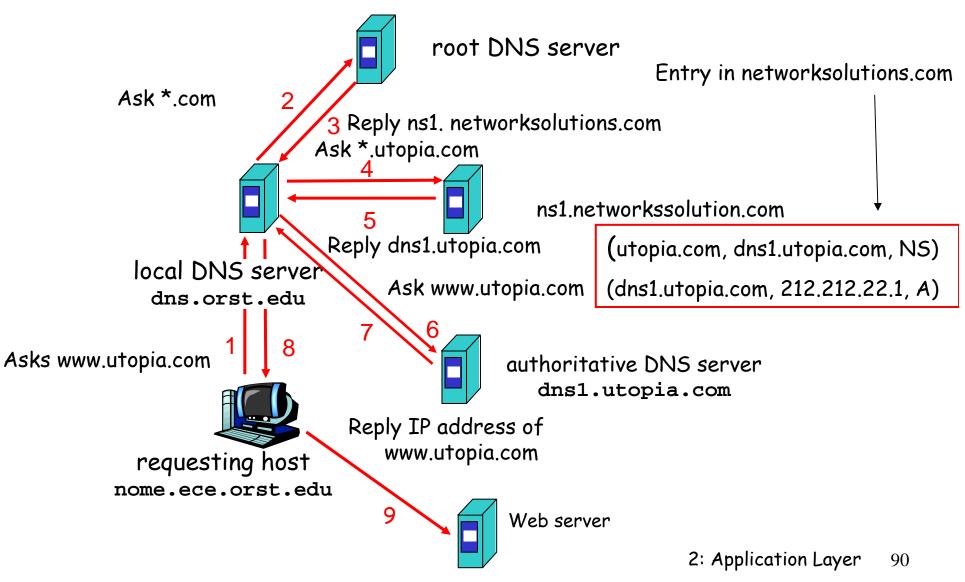

# Inserting records into DNS

- Example: just created startup "Utopia"
- Register name networkuptopia.com at a registrar (e.g., Network Solutions)
  - Need to provide registrar with names and IP addresses of your authoritative name server (primary and secondary)
  - Registrar inserts two RRs into the com TLD server:

(utopia.com, dns1. utopia.com, NS)
(dns1.utopia.com, 212.212.22.1, A)

Put in authoritative server Type A record for www.networkuptopia.com and Type MX record for networkutopia.com

## <u>How do people get the IP address</u> of your Web site?

# Chapter 2: Application layer

- 2.1 Principles of network applications
- □ 2.2 Web and HTTP
- 2.3 Electronic Mail
   SMTP, POP3, IMAP
- 2.4 Socket
  - programming with TCP
- 2.5 Socket programming with UDP

2.6 DNS2.7 P2P file sharing

# P2P file sharing

## <u>Example</u>

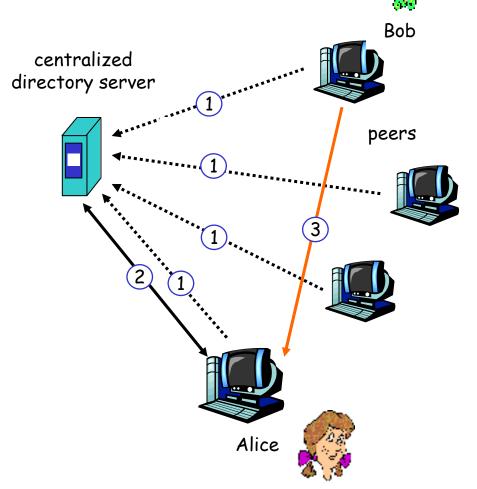

- Alice runs P2P client application on her notebook computer
- Intermittently connects to Internet; gets new IP address for each connection
- □ Asks for "Hey Jude"
- Application displays other peers that have copy of Hey Jude.

- Alice chooses one of the peers, Bob.
- File is copied from Bob's PC to Alice's notebook: HTTP
- While Alice downloads, other users uploading from Alice.
- Alice's peer is both a Web client and a transient Web server.
- All peers are servers = highly scalable!

# P2P: centralized directory

original "Napster" design

- 1) when peer connects, it informs central server:
  - IP address
  - o content
- 2) Alice queries for "Hey Jude"
- 3) Alice requests file from Bob

## P2P: problems with centralized directory

- □ Single point of failure
- Performance bottleneck
- Copyright infringement
  - (Kazaa located in Pacific island nation of Vanuatu)

file transfer is decentralized, but locating content is highly centralized!

# Query flooding: Gnutella

fully distributed

 no central server

 public domain protocol
 many Gnutella clients implementing protocol

## overlay network: graph

- edge between peer X
  and Y if there's a TCP
  connection
- all active peers and edges is overlay net
- Edge is not a physical link
- Given peer will typically be connected with < 10 overlay neighbors

# <u>History of Gnutella</u>

Two stages :

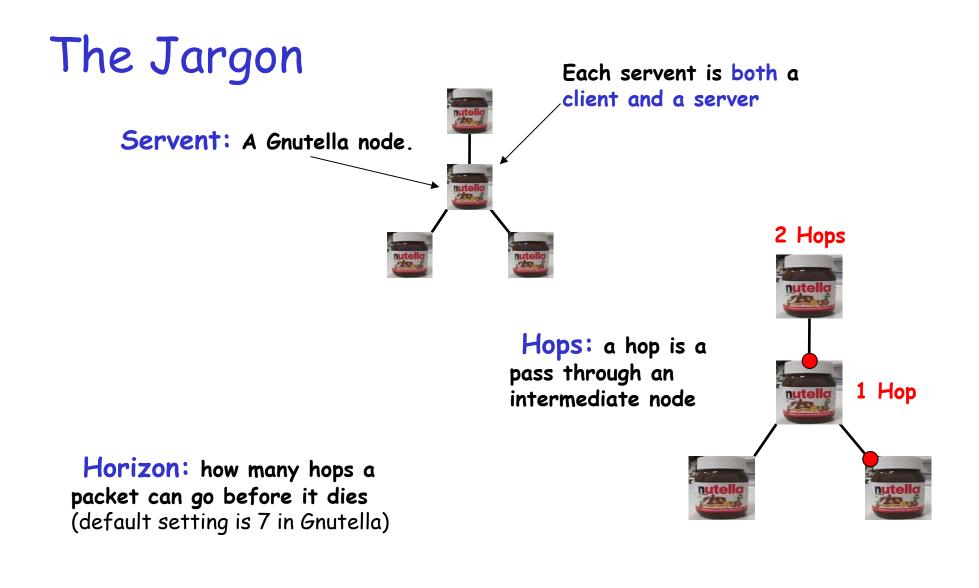

- 1. Join Network ... later
- 2. Use Network
  - 1. Discover other peers
  - 2. Search other peers

# Gnutella is a protocol for distributed search

- peer-to-peer comms
- decentralized model
- No third party lookup

### overlay network: graph

- edge between peer X and Y if there's a TCP connection
- all active peers and edges is overlay net
- Edge is not a physical link
- Given peer will typically be connected with < 10 overlay neighbors

# <u>Gnutella Descriptor</u>

- Gnutella messages that are passed around the Gnutella network

## 5 Descriptor Types

•Ping: used to actively discover hosts on the network. A *servent* receiving a *Ping* descriptor is expected to respond with one or more *Pong* descriptors.

•Pong: the response to a *Ping*.

(Each Pong packet contains a Globally Unique Identifier (GUID) plus address of *servent* and information regarding the amount of data it is making available to the network)

•Query: the primary mechanism for searching the distributed network. A *servent* receiving a *Query* descriptor will respond with a *QueryHit* if a match is found against its local data set.

•QueryHit: the response to a *Query*: contains IP address, GUID and search results

•Push: allows downloading from *firewalled servents* 

# <u>Gnutella Scenario</u>

#### Step 0: Join the network

### Step 1: Determining who is on the network

- "Ping" packet is used to announce your presence on the network.
- Other peers respond with a "Pong" packet.
- Also forwards your Ping to other connected peers
- A Pong packet also contains:
  - an IP address
  - port number
  - amount of data that peers is sharing
  - Pong packets come back via same route

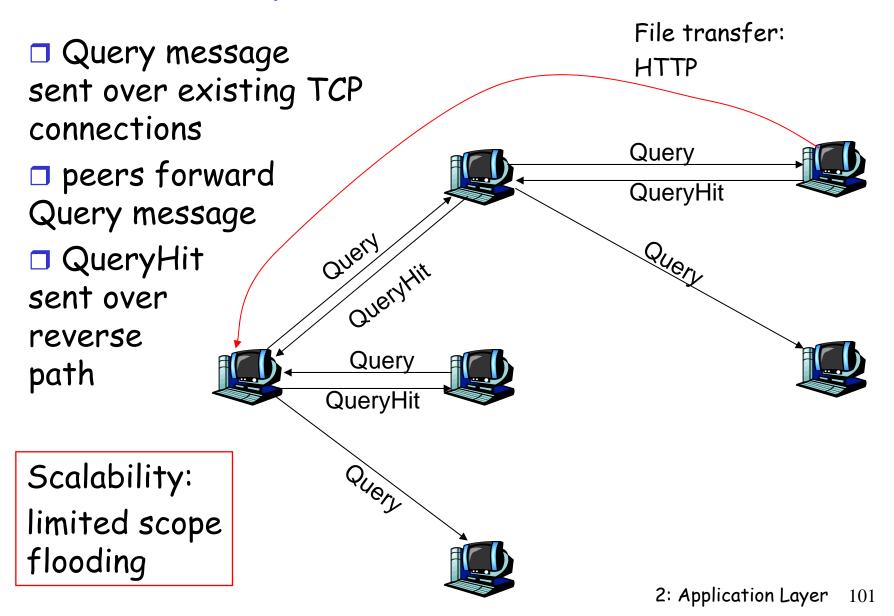

### Step 2: Searching

- Gnutella is a protocol for distributed search.
- Gnutella "Query" ask other peers if they have the file you desire (and have an acceptably fast network connection).
- A Query packet might ask, "Do you have any content that matches the string 'Homer"?
- Peers check to see if they have matches & respond (if they have any matches) & send packet to connected peers
- Continues for TTL

### Step 3: Downloading

- Peers respond with a "QueryHit" (contains contact info)
- File transfers use direct connection using HTTP protocol's GET method
- When there is a firewall a "Push" packet is used reroutes via Push path

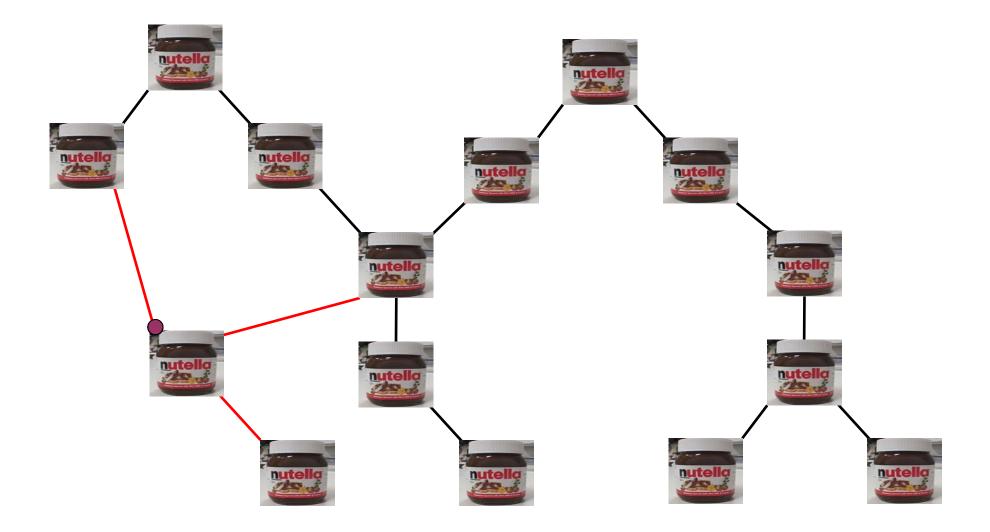

# Gnutella: protocol

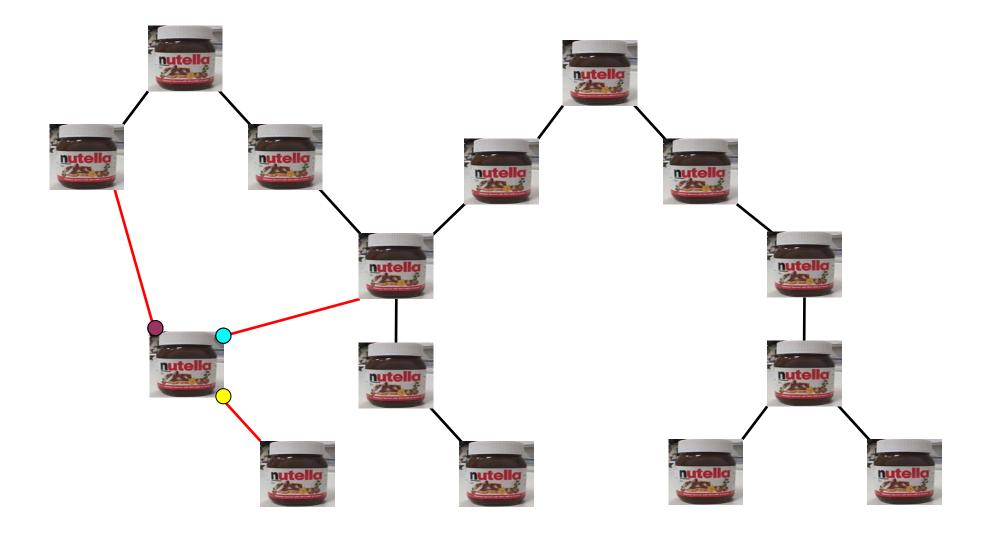

# Gnutella: Peer joining

- Joining peer X must find some other peer in Gnutella network: use list of candidate peers
- 2. X sequentially attempts to make TCP with peers on list until connection setup with Y
- 3. X sends Ping message to Y; Y forwards Ping message.
- 4. All peers receiving Ping message respond with Pong message
- 5. X receives many Pong messages. It can then setup additional TCP connections

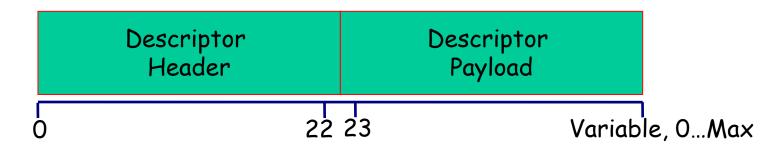

## Searching a Gnutella Network: From one Node

## Searching a Gnutella Network: All nodes

## Gnutella Descriptors

## Descriptor Types

•Ping: to actively discover hosts on the network.

•Pong: the response to a *Ping (*includes the GUID address of a connected *servent* and information regarding the amount of data it is making available to the network)

•Query: search mechanism

•QueryHit: the response to a *Query* (containing GUID and file info)

•Push: mechanism for *firewalled servents* 

## Gnutella Descriptor Header

|        | Descriptor ID | Payload<br>Descriptor | TTL     | Hops | Payload<br>Length |    |
|--------|---------------|-----------------------|---------|------|-------------------|----|
| Г<br>0 | 1             | 6 1                   | l<br>.7 | 18   | 19                | 22 |

• Descriptor ID: a unique identifier for the descriptor on the network (16-byte string)

• Payload Descriptor: 0x00 = Ping: 0x01 = Pong: 0x40 = Push: 0x80 = Query: 0x81 = QueryHit

• TTL: *Time To Live or Horizon.* Each *servent* decrements the TTL before passing it on - when TTL = 0, it is no longer forwarded.

• Hops: counts the number of hops the descriptor has traveled i.e. hops = TTL(0) when TTL expires

**Payload Length**: next descriptor header is located exactly *Payload Length* bytes from end descriptor header

# Gnutella Payload 1 - Ping Descriptor

### • Ping descriptors:

- no associated payload
- = zero length
- A Ping is simply represented by a *Descriptor Header* whose:
  - Payload\_ Length field is 0x0000000.
  - Payload\_Descriptor field = 0x00

## Gnutella Payload 2 - Pong

|   | Port | IP Address | Number of<br>files Shared | Number Of<br>Kilobytes Shared |   |
|---|------|------------|---------------------------|-------------------------------|---|
| 0 | ź    | 2          | 6                         | 10 1                          | 3 |

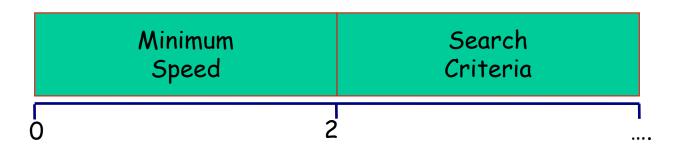

• Port: port which responding host can accept *incoming* connections.

• IP Address: IP address of the responding host (big-endian)

• Number of Files Shared: number of files responding host is sharing on the network

• Number of Kilobytes Shared: kilobytes of data responding host is sharing on the network.

## Gnutella Payload 3 - Query

• Minimum Speed: minimum speed (in kb/second) of *servents* that should respond to this message.

 A Servent receiving a Query descriptor with a minimum speed field of n kb/s should only respond with a QueryHit if it is able to communicate at a speed >= n kb/s

• Search Criteria: A nul (i.e. 0x00) terminated search string - maximum length is bound by *Payload\_Length* field of the descriptor header.

• e.g. "myFavouriteSong.mp3"

## Gnutella Payload 4 - QueryHit

|   | Number<br>Of Hits | Port | IP Address | Speed | Result<br>Set | Servent<br>Identifier |
|---|-------------------|------|------------|-------|---------------|-----------------------|
| δ | 1                 |      | 3 7        | 7 1   | 1 N           | N+16                  |

• Number of Hits: number of query hits in the result set

- Port: port which the responding host can accept incoming connections
- IP Address: IP address of the responding host (big-endian)
- Speed: speed (in kb/second) of the responding host

• **Result Set:** set of *Number\_of\_Hits* responses to the corresponding Query with the following structure:

- File Index: ID of file matching the corresponding query assigned by the responding host
- File Size: size (bytes) of this file
- File Name: name of the file (double-nul (i.e. 0x0000) terminated)

• Servent Identifier: servent network ID (16-byte string), typically function of servent's network address - instrumental in the operation of the *Push Descriptor* ....

2: Application Layer 110

## Gnutella Payload 5 - Push

|   | Servent<br>Identifier | File Index | IP Address | Port |         |
|---|-----------------------|------------|------------|------|---------|
| 0 | 1                     | l<br>6     | 20         | 24   | ר<br>25 |

• Servent Identifier: target servent network ID (16-byte string) requested to push file (with given index *File\_Index*)

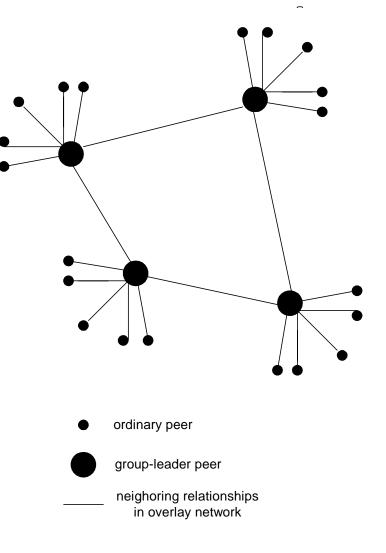

• File Index: ID of the file to be pushed from the target servent

• **IP** Address: IP address of target host which file should be pushed (big-endian forma)

• Port: port on target host which file should be pushed

## Exploiting heterogeneity: KaZaA

- Each peer is either a group leader or assigned to a group leader.
  - TCP connection between peer and its group leader.
  - TCP connections between some pairs of group leaders.
- Group leader tracks the content in all its children.

# KaZaA: Querying

- Each file has a hash and a descriptor
- Client sends keyword query to its group leader
- Group leader responds with matches:
   For each match: metadata, hash, IP address
- If group leader forwards query to other group leaders, they respond with matches
- Client then selects files for downloading
  - HTTP requests using hash as identifier sent to peers holding desired file

Limitations on simultaneous uploads

- Request queuing
- Incentive priorities
- Parallel downloading

# Chapter 2: Summary

Our study of network apps now complete!

- Application architectures
  - client-server
  - P2P
  - o hybrid
- application service requirements:
  - reliability, bandwidth, delay
- Internet transport service model
  - connection-oriented, reliable: TCP
  - o unreliable, datagrams: UDP

specific protocols:

- O HTTP
- SMTP, POP, IMAP
- DNS
- socket programming

# Chapter 2: Summary

## <u>Most importantly:</u> learned about *protocols*

- typical request/reply message exchange:
  - client requests info or service
  - server responds with data, status code
- message formats:
  - headers: fields giving info about data
  - data: info being communicated

- control vs. data msgs
  - in-band, out-of-band
- centralized vs. decentralized
- 🗖 stateless vs. stateful
- reliable vs. unreliable msg transfer
- "complexity at network edge"
