

Design Note #004

Keywords: Hardware UART

This document is originally distrubuted by AVRfreaks.net, and may be distributed, reproduced, and modified without restrictions. Updates and additional design notes can be found at: www.avrfreaks.net

Common Use of the AVR Hardware UART

Introduction

This document provides a short introduction to the use of the hardware UART present in most AVR devices. There are several existing application notes regarding the UART (AVR304, AVR305 and AVR306). Issues outside the boundaries of this document might be resolved in one of these.

Overview The following registers affect the AVR hardware UART:

• UDR – UART Data Register

Actually two physically separated registers sharing the same I/O address. Transmitted and received data are written to, and read from this register.

• USR – UART Status Register

This register contains status information bits, the most commonly used being Receive Complete, Transmit Complete, and Data Register Empty.

• UCR – UART Control Register

In this register, the transmission interrupts are enabled/disabled, as well as the transmitter/receiver themselves. Specifics about the data word are also set here.

• UBRR – UART Baud Rate Register

In this register, the transmission BAUD rate is set. The datasheet on every AVR part contains tables of the most common baudrate settings, as well as general equations to set the correct value in the UBR register if the tables do not cover the parameters.

The operation of the UART is not very complex. In the following, two examples will be presented: Polled and Interrupt controlled UART. The latter can be expanded further as suggested in the application note AVR306.

Code examples

The following code should be self-explanatory if the comments are read.

Polled UART

```
C Code
                                                     Assembly
//include definitions for the AT90S8515
                                                         ; include definitions for the AT90S8515
#define ENABLE_BIT_DEFINITIONS
                                                         .include "8515def.inc"
#include <io8515.h>
                                                         ;definitions
//initialize UART
                                                         .def temp = r16 ;temporary data
void InitUART(unsigned char baudrate)
                                                             lditemp,low(RAMEND)
{
    UBRR = baudrate;
                                                             outSPL, temp
     //enable receiver and transmitter
                                                             lditemp,high(RAMEND)
    UCR |= (1<<RXEN) | (1<<TXEN);
                                                             outSPH,temp;init Stack Pointer
}
                                                             rjmpstart;reset handler
                                                         ;initialize UART
//receive a byte
unsigned char ReceiveByte(void)
                                                         initialize:
                                                                           ;baudrate in temp
                                                             out UBRR, temp
{
    //polls on receive complete
                                                             ;enable receiver and transmitter
    while(!(USR & (1<<RXC)))</pre>
                                                             ldi
                                                                   temp,(1<<RXEN) | (1<<TXEN)
                                                                   UCR, temp
